

# Git General Training

## Git Best Practices

Git -> manage AI tips

Deep inspection of basic commands

Ilya Rokhkin

# Git – meaning?

What does the word Git mean?

# GIT Overview

The screenshot shows a Wikipedia page titled "Git (slang)". The page header includes the Wikipedia logo, a "Talk" tab (which is selected), and "Read" and "Edit" buttons. Below the header, the title "Git (slang)" is displayed in large, bold, black font. A sub-header "From Wikipedia, the free encyclopedia" follows. The main content starts with a definition: "Git is a term of insult with origins in English denoting an unpleasant, silly, incompetent, ...". The page footer contains a navigation bar with links like "Main page", "About", "Help", "Community portal", "Recent changes", and "Log in". Below the footer, there's a toolbar with icons for "T", "LOG", "Duty", "R", "W", "icinga", and "Grok". The main content area discusses the name "git" and its origin from British English slang.

Article Talk Read Edit

## Git (slang)

From Wikipedia, the free encyclopedia

*Git is a term of insult with origins in English denoting an unpleasant, silly, incompetent, ...*

<https://en.wikipedia.org/wiki/Git>

T LOG Duty R W icinga Grok

### Naming [ edit ]

Torvalds quipped about the name *git* (which means *unpleasant person* in *British English* slang): "I'm an egotistical bastard, and I name all my projects after myself. First 'Linux', now 'git'."<sup>[23][24]</sup> The man page describes Git as "the stupid content tracker".<sup>[25]</sup>

# Agenda:

## 1. Basic concepts and commands in deep dive

- Git Architecture, data model
- DVCS, Repository, Commit, Parent Commit, Tree, Blob, Index, Refs
- Basic commands to work in the Repository and outside.
- Sharing work with peers.
- Advanced commands explained (rebase -i, cherry-pick, squash, revert of all kinds, patch, reflog )
- Best practices (rebase, commits per change, feature branch, etc.)
- How to manage AI changes in Git

## 2. Practical part, lab work

- 13 exercises from, basic to advanced
- Best practices and manage AI changes exercise

# GIT Overview

- Quick and efficient
- Expedite distributed development
- Atomic transactions, commit, cross repository
- Commits (Change) management
- A clear internal design
- Suited to handle everything from small to very large projects with speed and efficiency
- Support and encourage branched development

# About myself:

Author: Ilya Rokhkin

+ Role: DevOps Engineer @ CloudOps DevOps Team

- Role: Harmony Connect DevOps

+ GitHub EMU Owner

Experience:

20+ years in VCS

Git trainer

+ (CHKP, Freelancer)

- (Intel, Marvell)

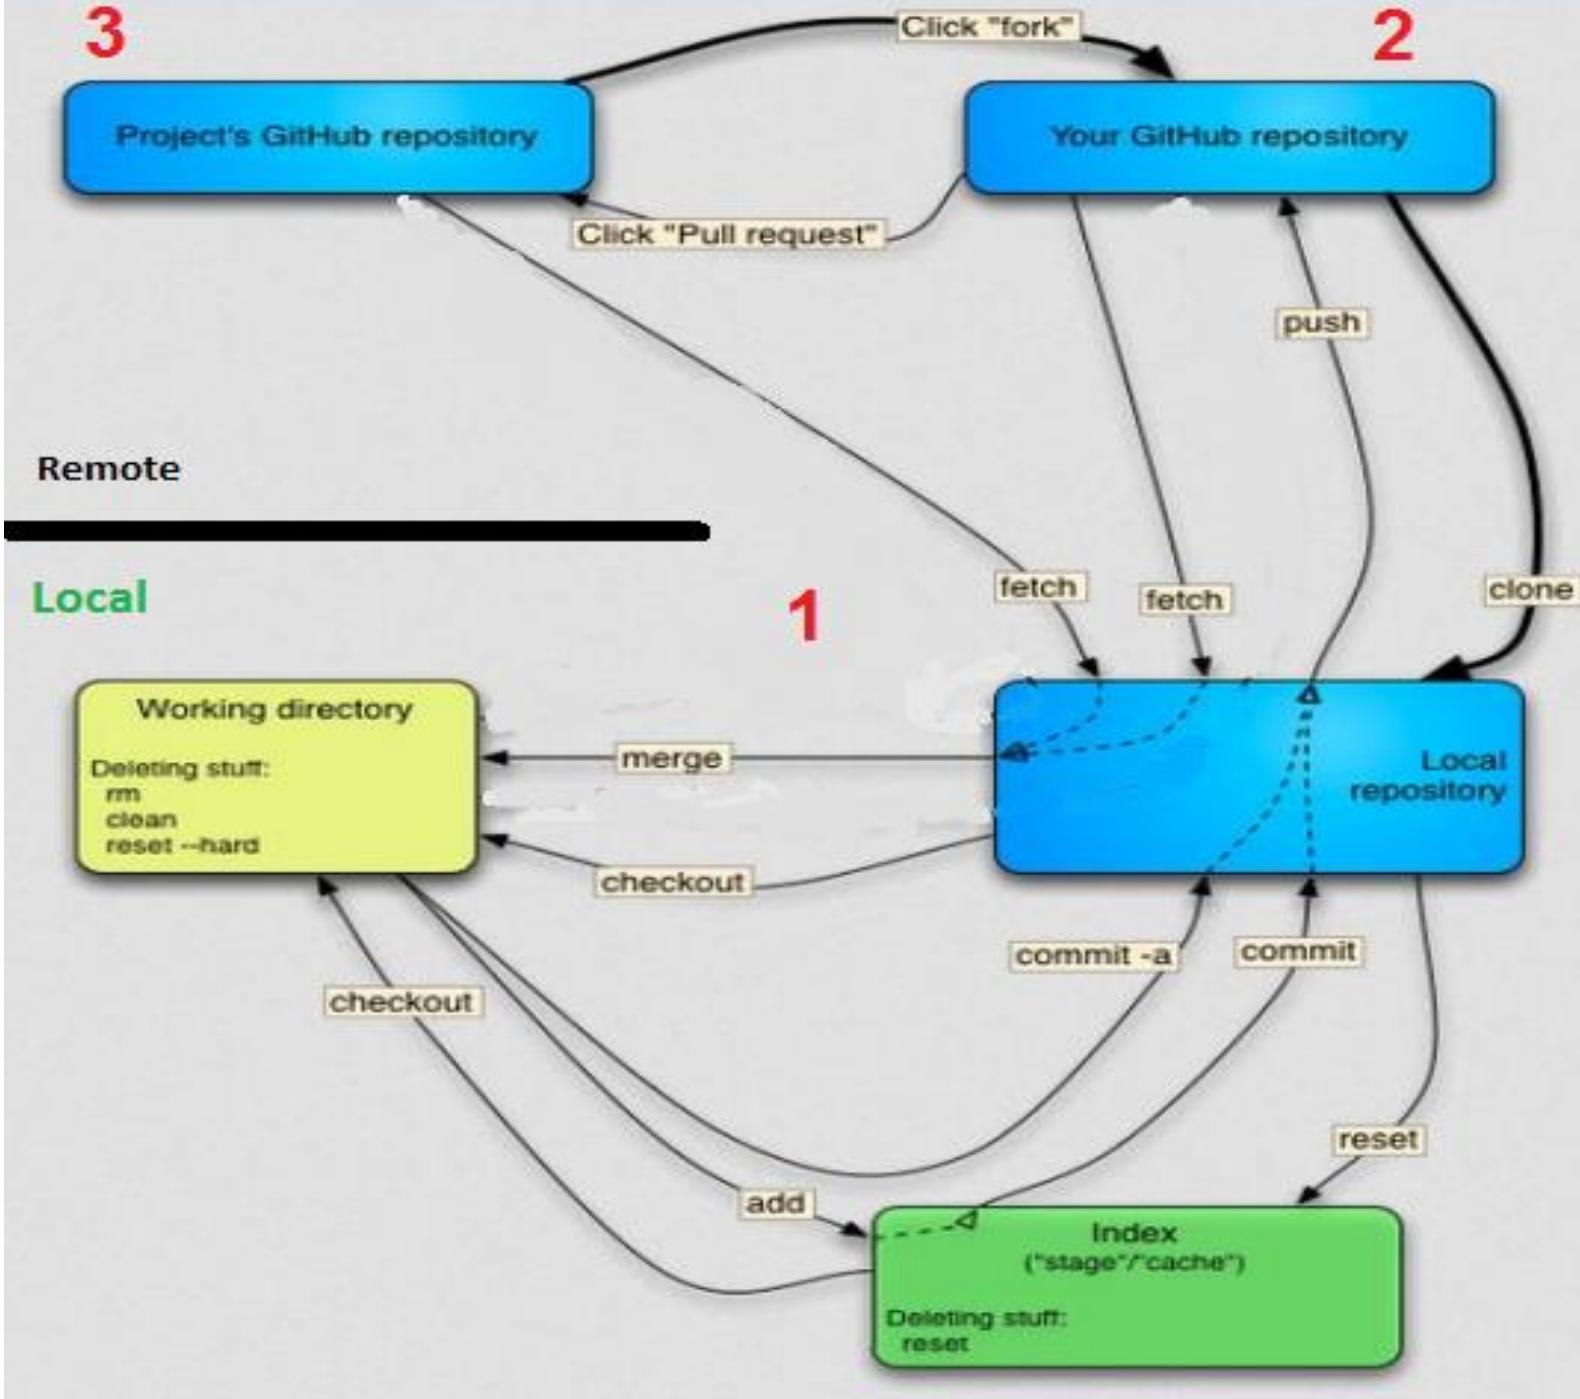

Hebrew teacher

volunteer @ Ulpan

# GIT Architecture

1. Your Local repo
2. Your Remote (Origin) repo
3. Common (Community) Remote Origin repo

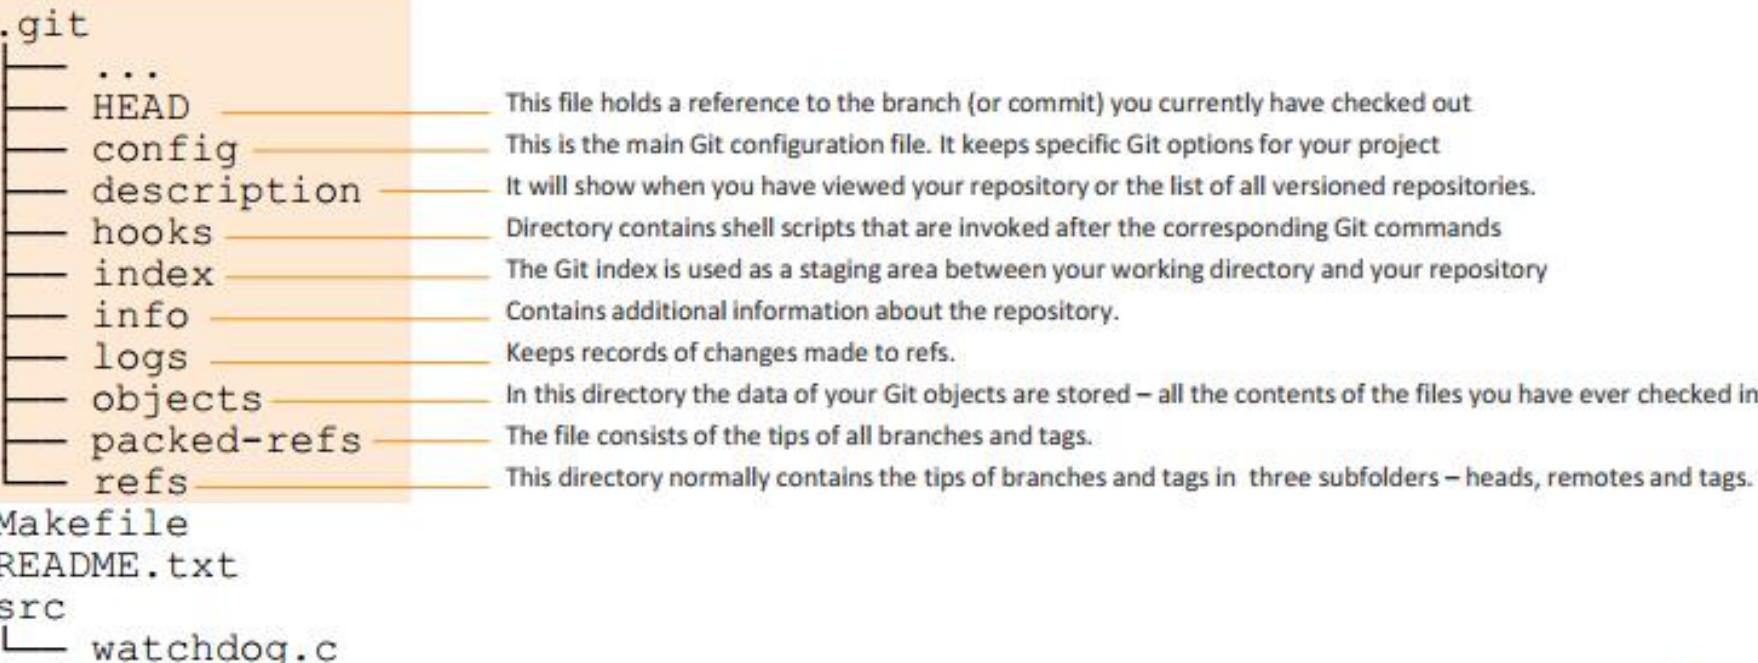

# Demo

## Lab 1 - 2

- We will configure your git user and e-mail  
Will create a remote, bare repository in the home directory
  - Clone it to work repository1 in the home directory also, add, commit, and push
- Restructure files, add, commit, and push

# Git repository structure (.git)

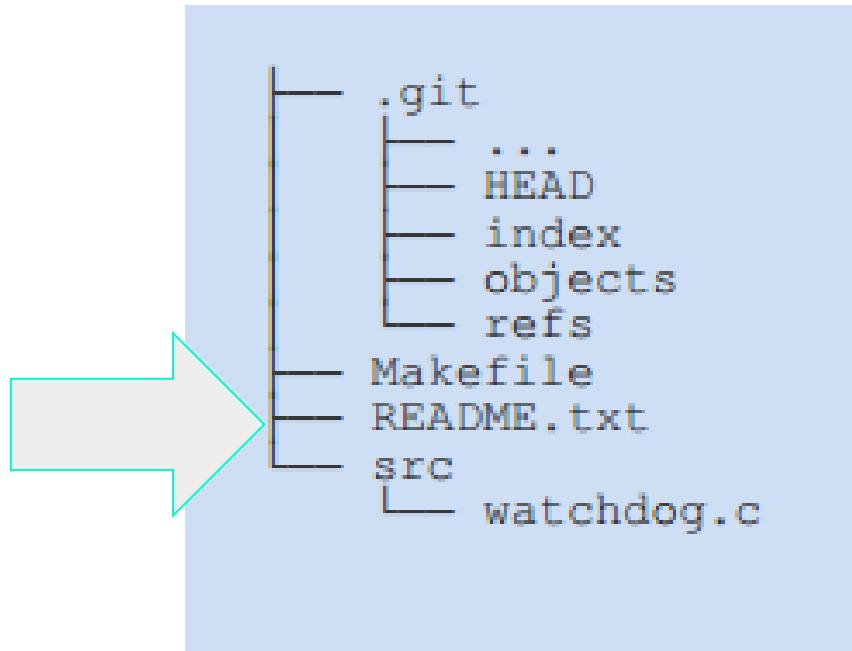

```
$ ls -al
total 11
drwxr-xr-x  7 sheta  Administ  4096 Dec  3 15:17 .
drwxr-xr-x  3 sheta  Administ  4096 Nov 30 11:26 ..
-rw-r--r--  1 sheta  Administ   23 Nov 30 11:09 HEAD
-rw-r--r--  1 sheta  Administ   363 Nov 30 11:46 config
-rw-r--r--  1 sheta  Administ   73 Nov 29 17:03 description
drwxr-xr-x  2 sheta  Administ  4096 Nov 29 17:03 hooks
-rw-r--r--  1 sheta  Administ   32 Nov 30 11:26 index
drwxr-xr-x  2 sheta  Administ     0 Nov 29 17:03 info
drwxr-xr-x  3 sheta  Administ     0 Nov 29 17:03 logs
drwxr-xr-x 25 sheta  Administ  4096 Nov 30 11:08 objects
-rw-r--r--  1 sheta  Administ   94 Nov 29 17:03 packed-refs
drwxr-xr-x  5 sheta  Administ    0 Nov 30 11:07 refs
```

# The Working Tree

- The working tree has all files and folders as found in your HEAD, plus the changes you made since your last commit
- There is only ONE main working tree per repository (and only 1 .git folder as well)

The Working Tree

# States of files in Working Tree

- **Untracked** – in the repository folder, git does not keep a version of it.
- **Modified** – tracked, modified since last stage or commit.
- **Staged** – a snapshot of the file, ready to be committed. Even if modified, git will still keep the snapshot.
- **Committed** – version of file saved in repository DB

# Objects

There are only **4** object types in GIT:

**Type** – “blob”, “tree”, “commit”, “refs” (branch/tag).

A "blob" is basically like a file – it is used to store the content of a source file.

A "tree" is basically like a directory - it references a group of other trees (subdirectories) and/or blobs (files).

A "commit" points to a single tree, marking it as what the project looked like at a certain point in time. Keeps changed files since the last commit, author of the changes, a reference to the parent commit(s), etc.

A “refs” is a way to mark a specific commit as special in some way. It is usually used to tag certain commits as specific releases or something along those lines.

# Objects cont.

Almost all the GIT is built around manipulating this simple structure of four different object types. It is sort of it's own little file system that sits on top of your machine's file system.

Let's say we have a small project that looks like this:

```
$>tree  
.  
|-- README  
`-- lib  
    |-- inc  
    |   '-- tricks.rb  
    '-- mylib.rb  
  
2 directories, 3 files
```

If we will commit this project to a GIT repository, it will be represented in GIT like this:

# Commit Object

98ca9..

commit	size
tree	0de24
parent	nil
author	Scott
committer	Scott
my commit message goes here and it is really, really cool	

0de24..

```

# The HEAD

- HEAD is a 'pointer' to the tip of the currently checked out branch
  - In a *detached HEAD* state, HEAD points directly to a commit
- Only one HEAD per repository

# Demo

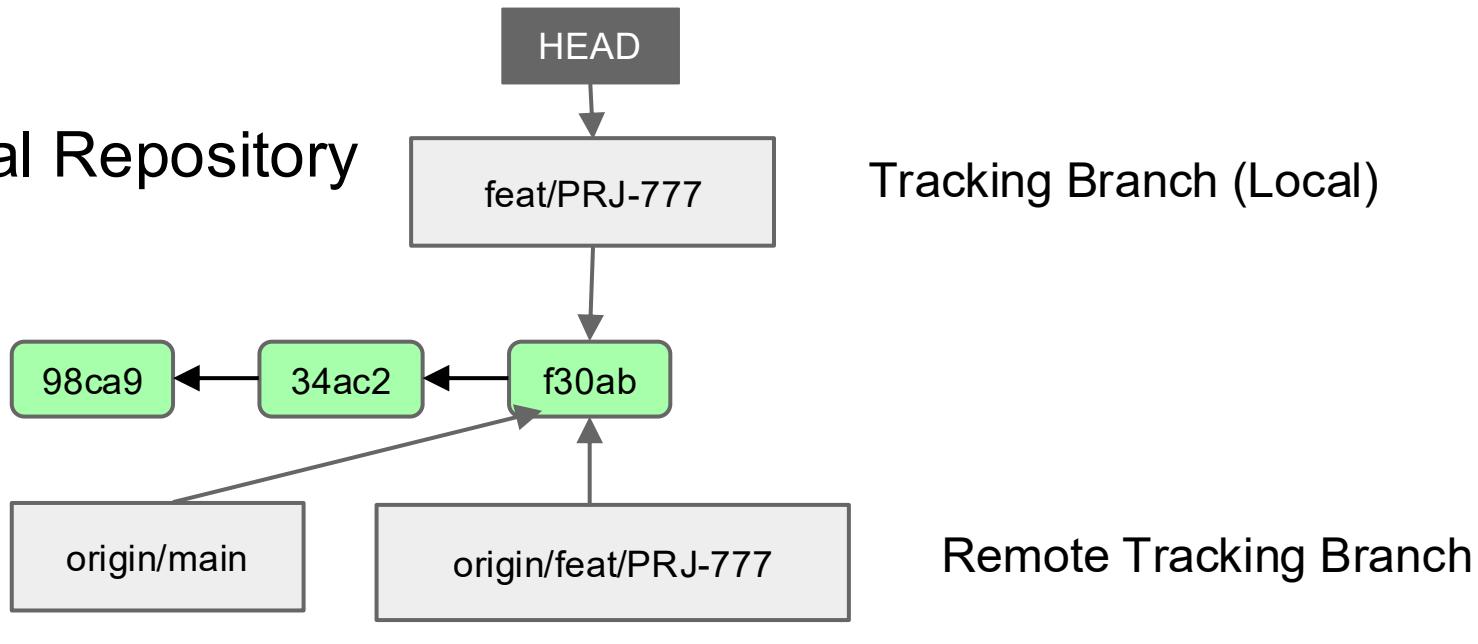

## Lab 3

Teamwork, parallel work:

- We will clone the second work repository2
- We will commit changes in both repositories
- Push and pull with silent rebase to apply the commit of one repo into another
- Overview results

# Rebasing Remote Tracking Branch

Local Repository

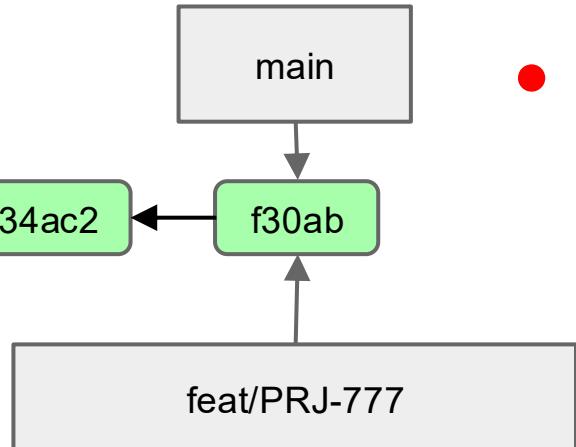

Tracking Branch (Local)

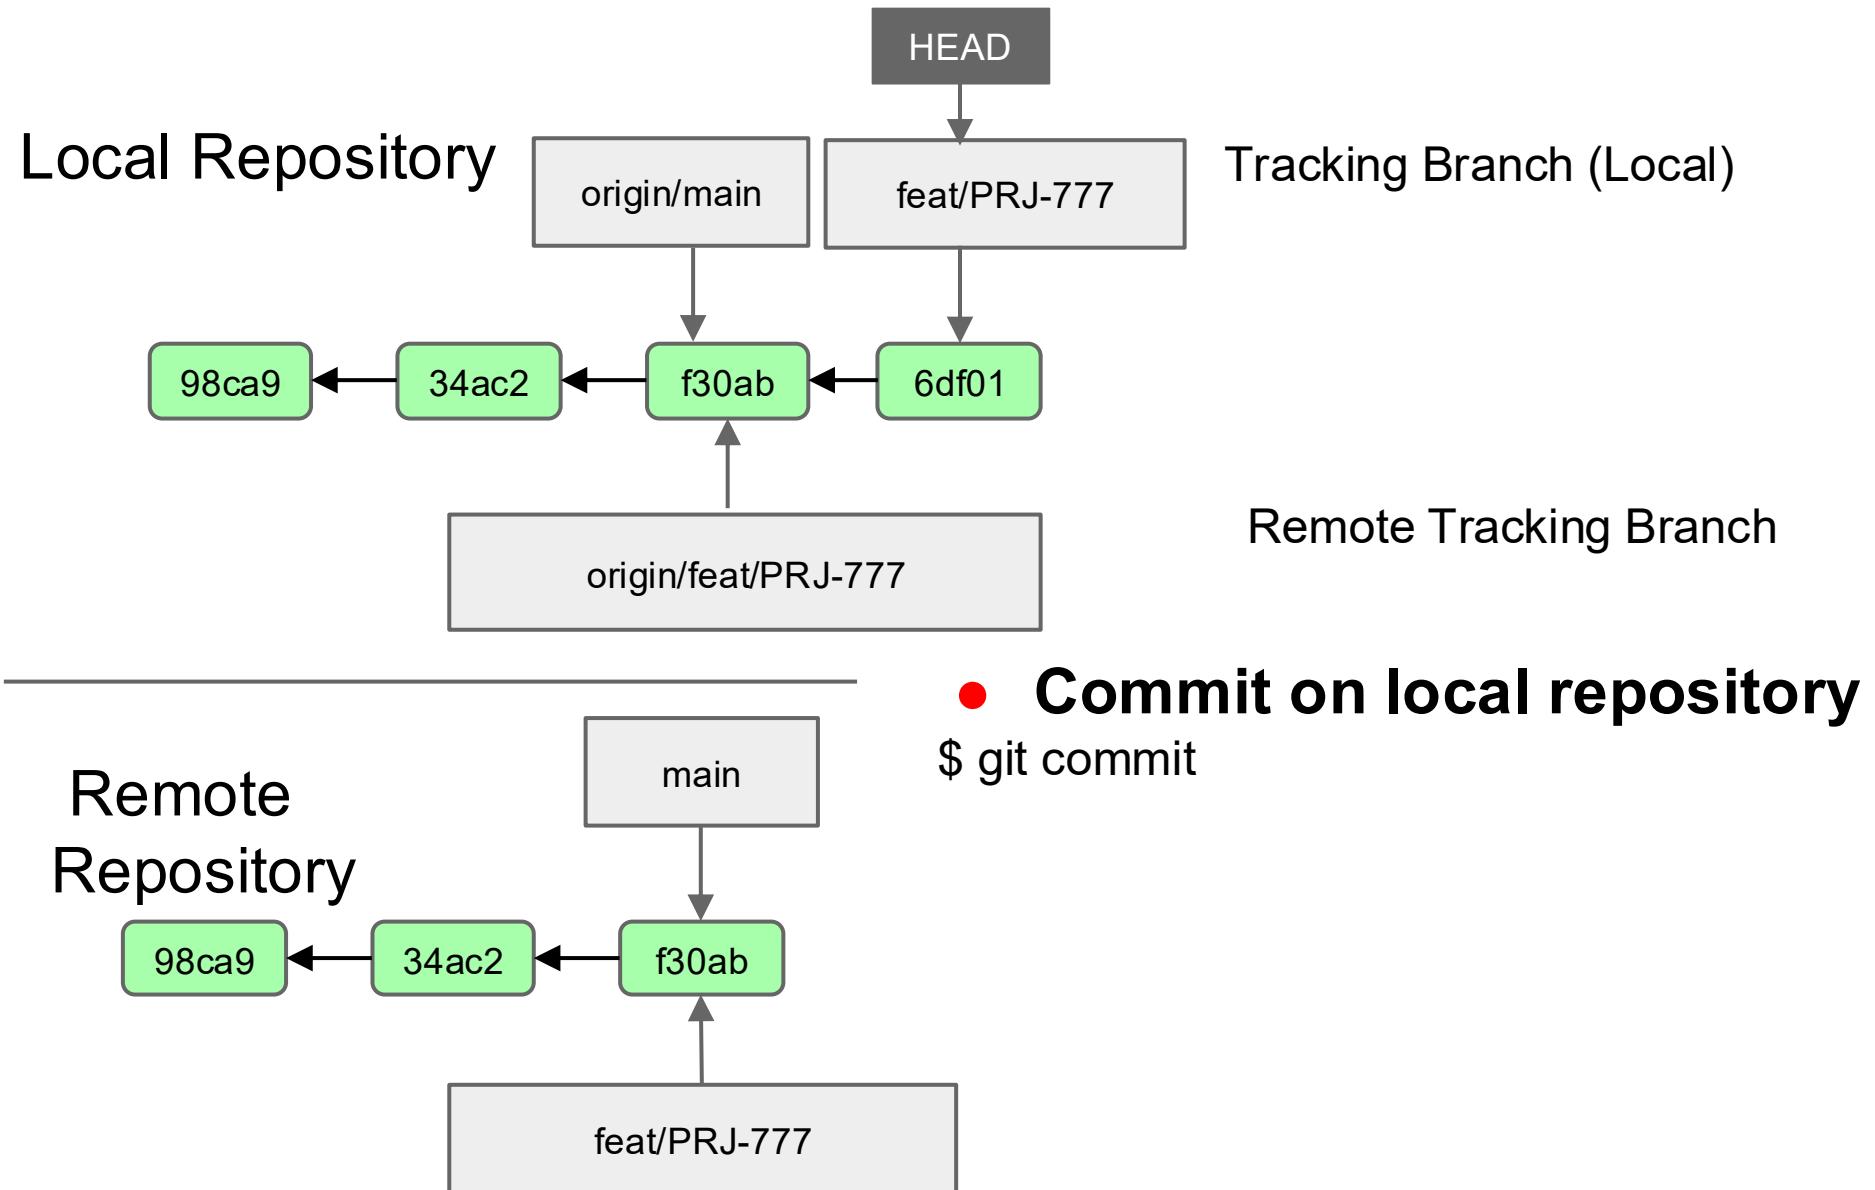

Remote Tracking Branch

Remote  
Repository

- 
- The diagram shows the history of the main branch in a remote repository. It consists of three green boxes labeled "98ca9", "34ac2", and "f30ab" arranged horizontally. A downward arrow points from "f30ab" to a light grey box labeled "main".
- After clone/pull Remote Tracking Branch and Tracking (Local) branch pointing to the same commit

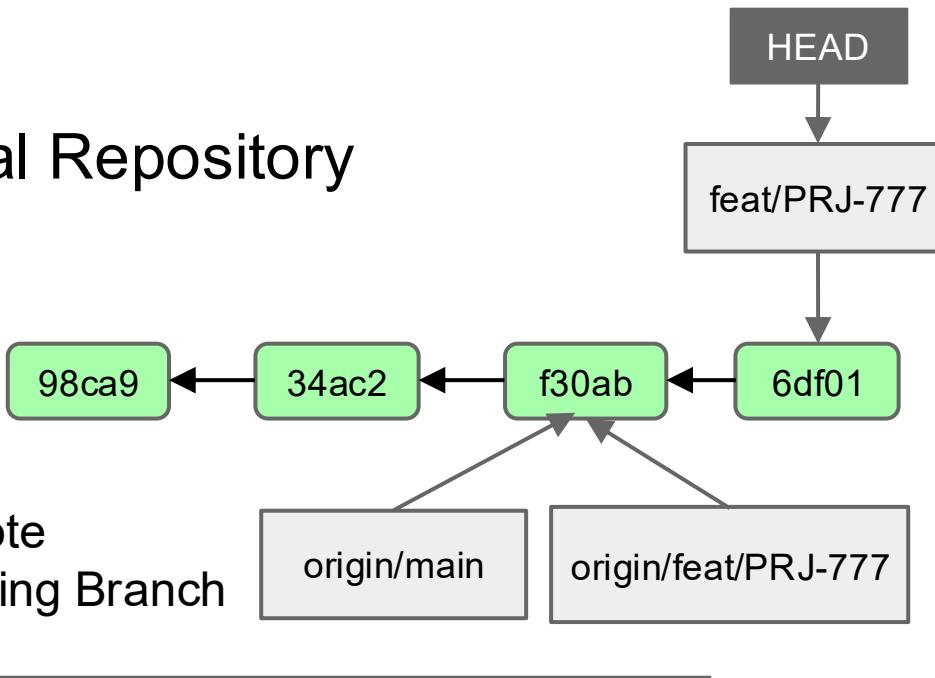

# Rebasing Remote Tracking Branch

Remote  
Tracking  
Branch  
and  
Tracking  
(Local)  
branch  
points to  
the same  
commit

Remote Repository

# Perils of rebase

- **Do not rebase commits that you have pushed to a public repository.**

If you follow that guideline, you'll be fine. If you don't, people will hate you, and you'll be scorned by friends and family.

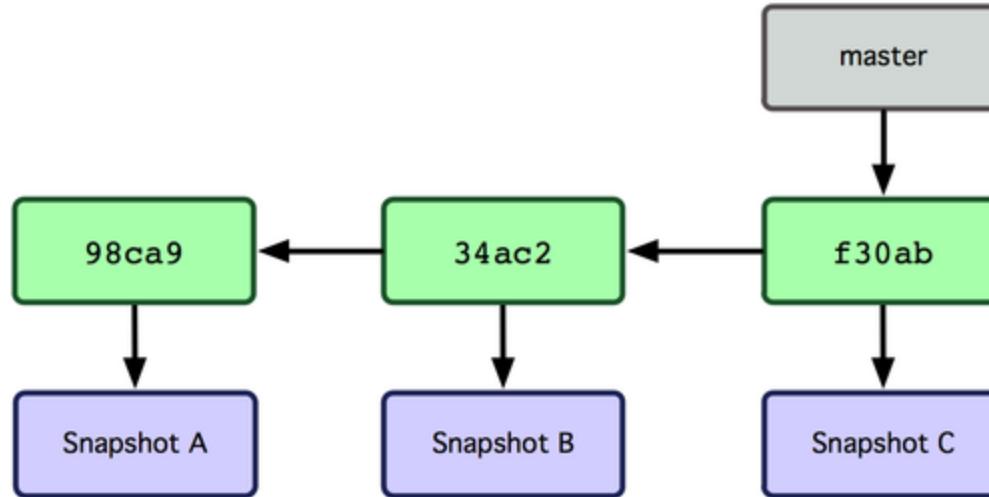

# Demo

## Lab 4

- Teamwork, parallel work with rebase, and conflict resolution:
- We will do commits in both repositories, with changes in the same line of the same file
- Pull with rebase, resolve conflicts, and save the resolution file
- Adding the file to the staging area means resolving the issue.
- Commit and push

# Git branches

- Git branch is simply a movable pointer to a commit

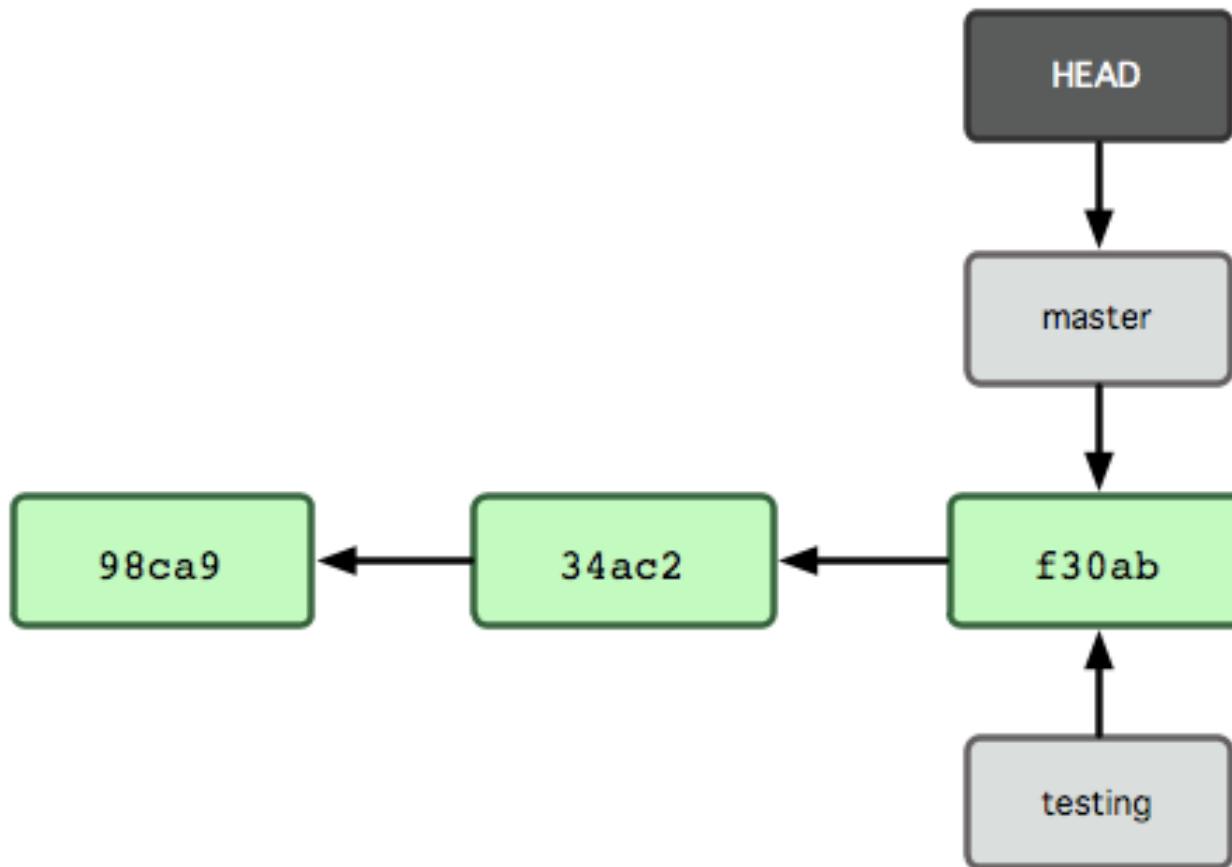

- Pointer moves forward automatically with each commit on a branch

# Creating new branch

- New branch creates a new reference

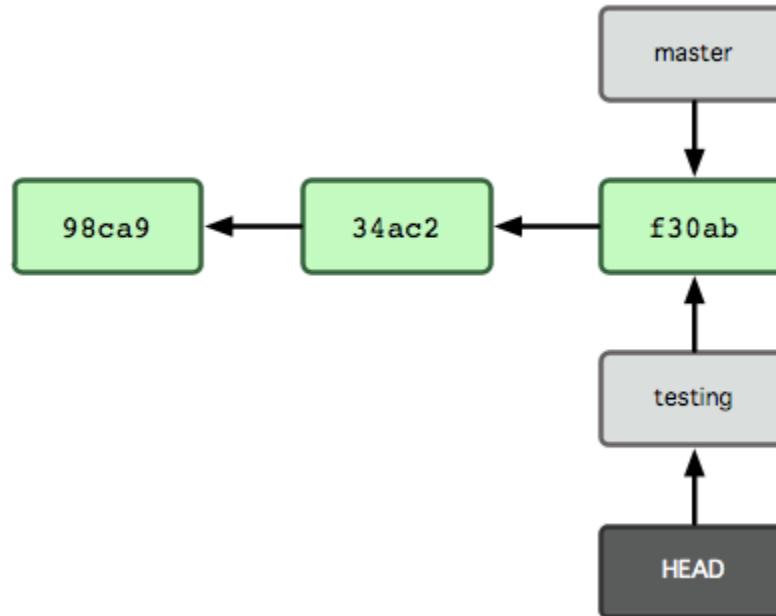

```
> git branch testing
```

# Switching to a branch

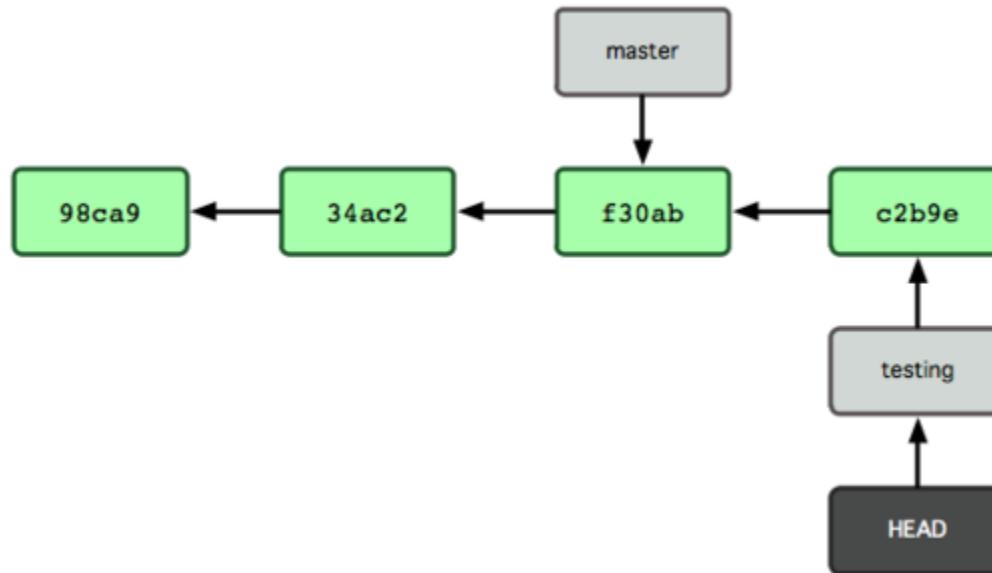

- Git checkout *branch-name* switches to an existing branch

```
> git checkout testing
```

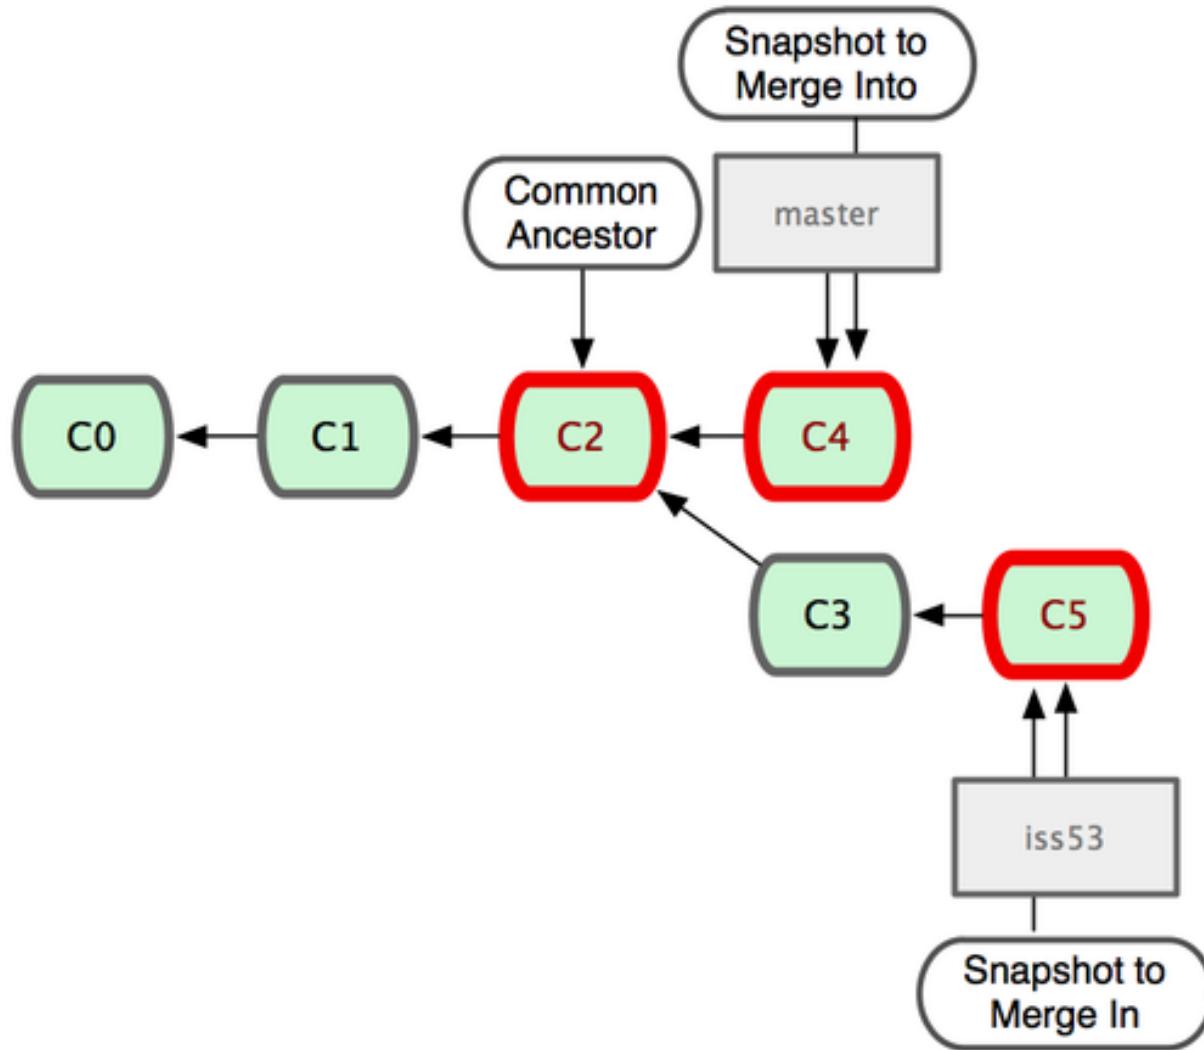

# New commit moves current branch

```
> vi file04.txt  
> git commit -a -m 'Commit message'
```

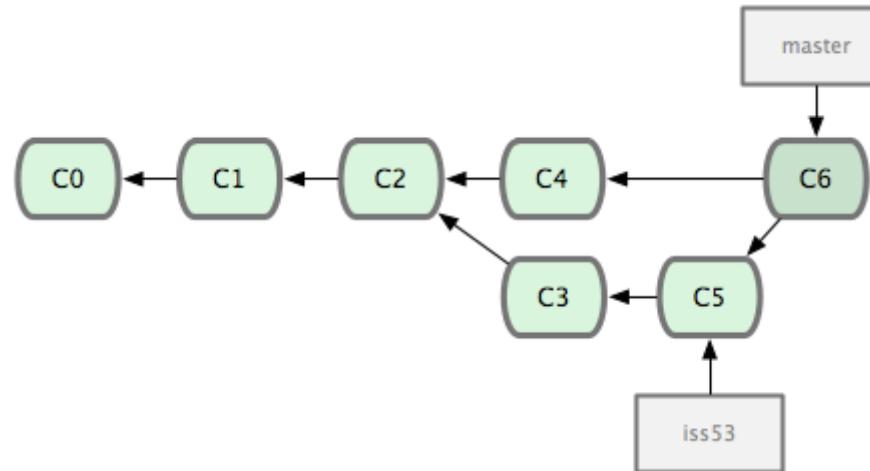

# Merging branches

# Merging branches (continued)

- As a result of merge Git creates a new commit, which has two parents:

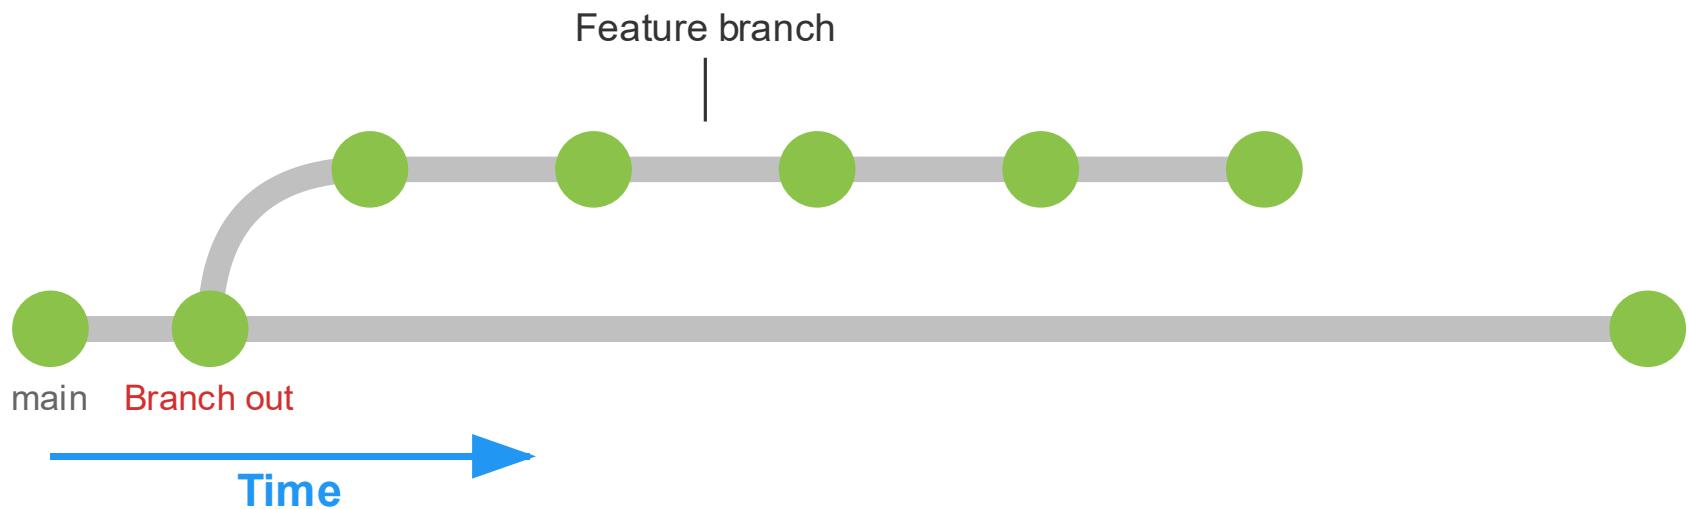

# Demo

## Lab 5 - 7

- We will create a tag
  - Create branch bugfix from the tag
    - I will do a bugfix commit in the bugfix branch
    - Check out the master branch and commit a new change
  - Merge bugfix branch
- Overview results

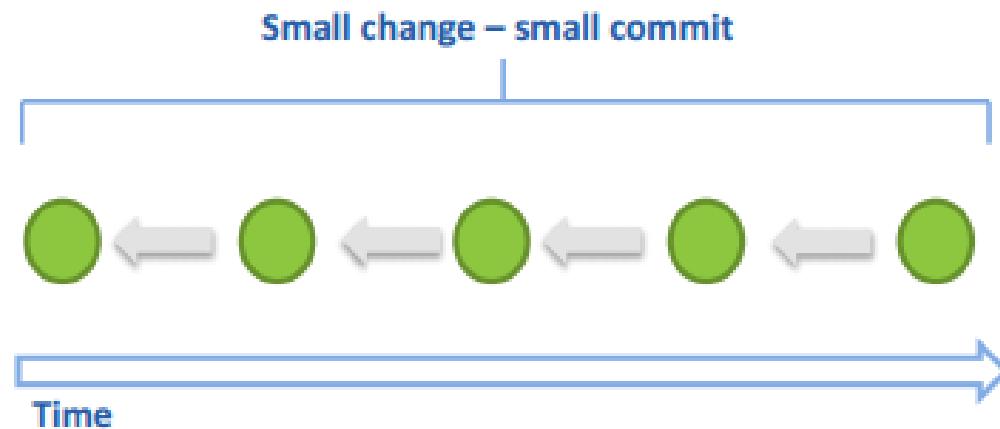

# Best practices – local feature branches

**Work on feature branches locally**

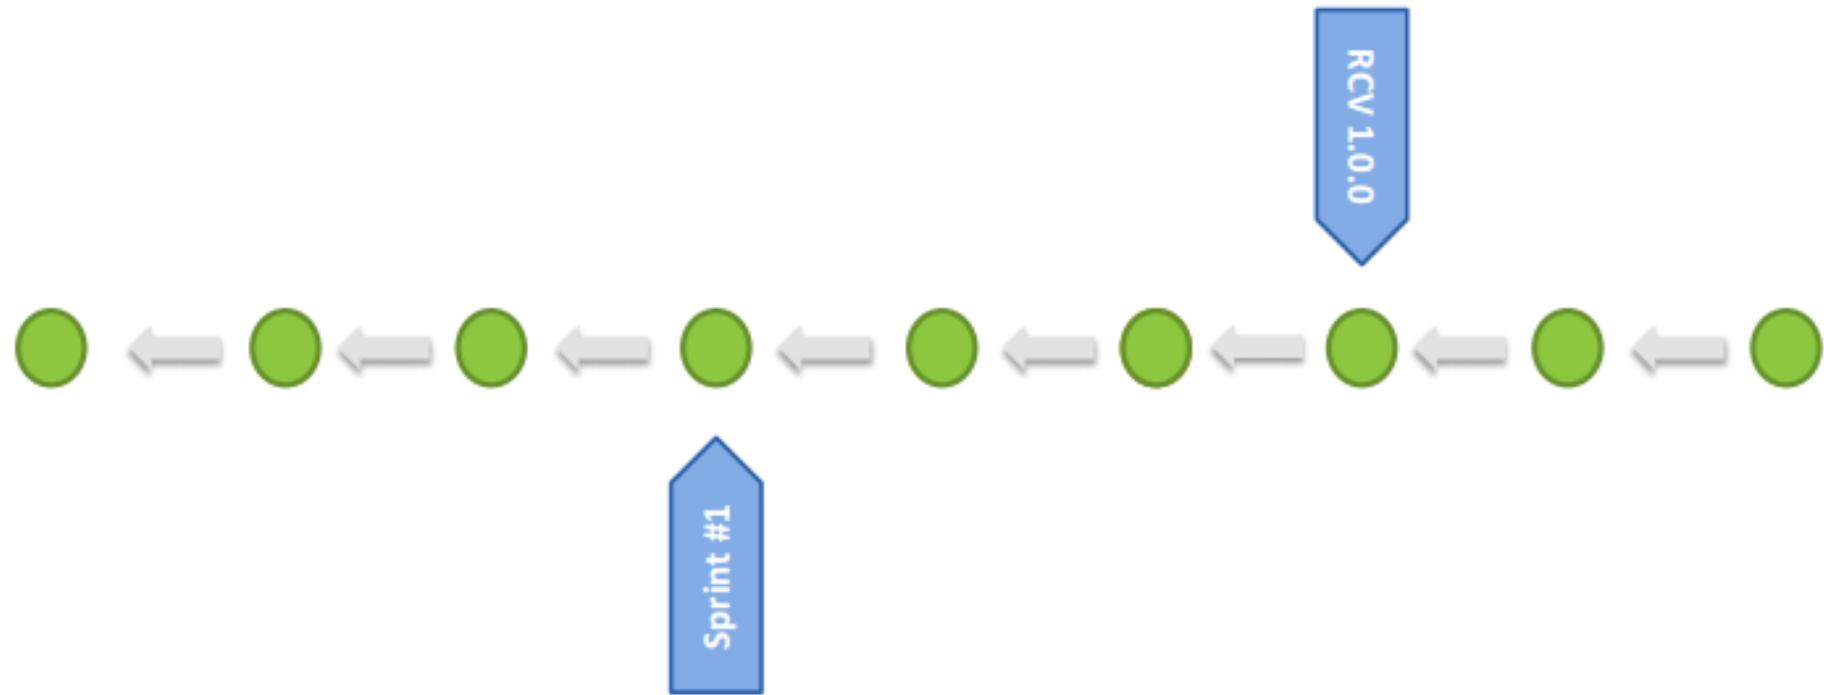

# Best practices – commit

Keep changes small wherever possible and commit frequently

# Best practices – tag milestones and important working changes!

Tag important milestones (for history and for accessibility)

**CLOUDEVOPS-4466:** Removing cron: '0 8-22 \* \* \*' (#15)

Removal cron from workflow  
Will be run on demand and not on GitHub

---  
Jira: CLOUDEVOPS-4466  
Branch: feat/CLOUDEVOPS-4466-gh-migration-remove-workflow  
w-cron

- **Concise commit message header from 50 to 70 chars for best readability, with Jira task ahead**
- **Meaningful message body**

# Best practices – Branch Layout

Git branches with type/JIRA-123-task-short-description

**Type:** fix, feat, release, doc, etc. – type of task you do

**Slash:** / - it is folder/file separation, you can select all fixes

**Jira:** JIRA-123 - CHKP Jira task

**Short Description of the task:** -task-short-description

Examples:

```
$ git branch
```

```
feat/CLOUDEVOPS-4335-check-gitlab-blocked-urls
```

```
fix/CLOUDEVOPS-4466-gh-migration-fix-mirroring
```

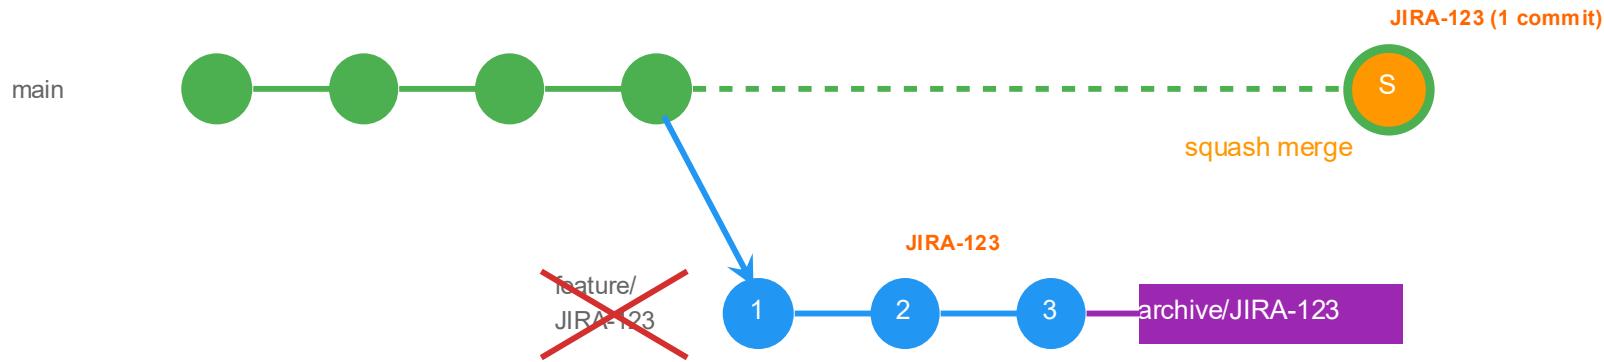

```
feat/CLOUDEVOPS-4466-gh-migration-remove-workflow-cron
```

```
* feat/CLOUDEVOPS-4674-add-environments-and-their-vars
```

```
main
```

# Best practices – clean up local branches

**Delete local and remote branches, once the code is merged to the main branch**

## Cleanup Commands:

1. `git tag archive/JIRA-123 feature/JIRA-123`
2. `git fetch --prune`
3. `git branch -D feature/JIRA-123`

# Save branch history  
(push -tags if needed)

# Fetch and delete local and  
remote-tracking refs

# Force delete local branch

# Lab 8 - 10

- We will create branch bugfix2, from Release\_01  
Cherry-pick 1 commit from the master branch
- Undo modified file, undo staged file  
Undo the latest local commit, revert the pushed commit
- Stash meanwhile work aside, make a commit,  
return work from stash

# Lab 11 - 13

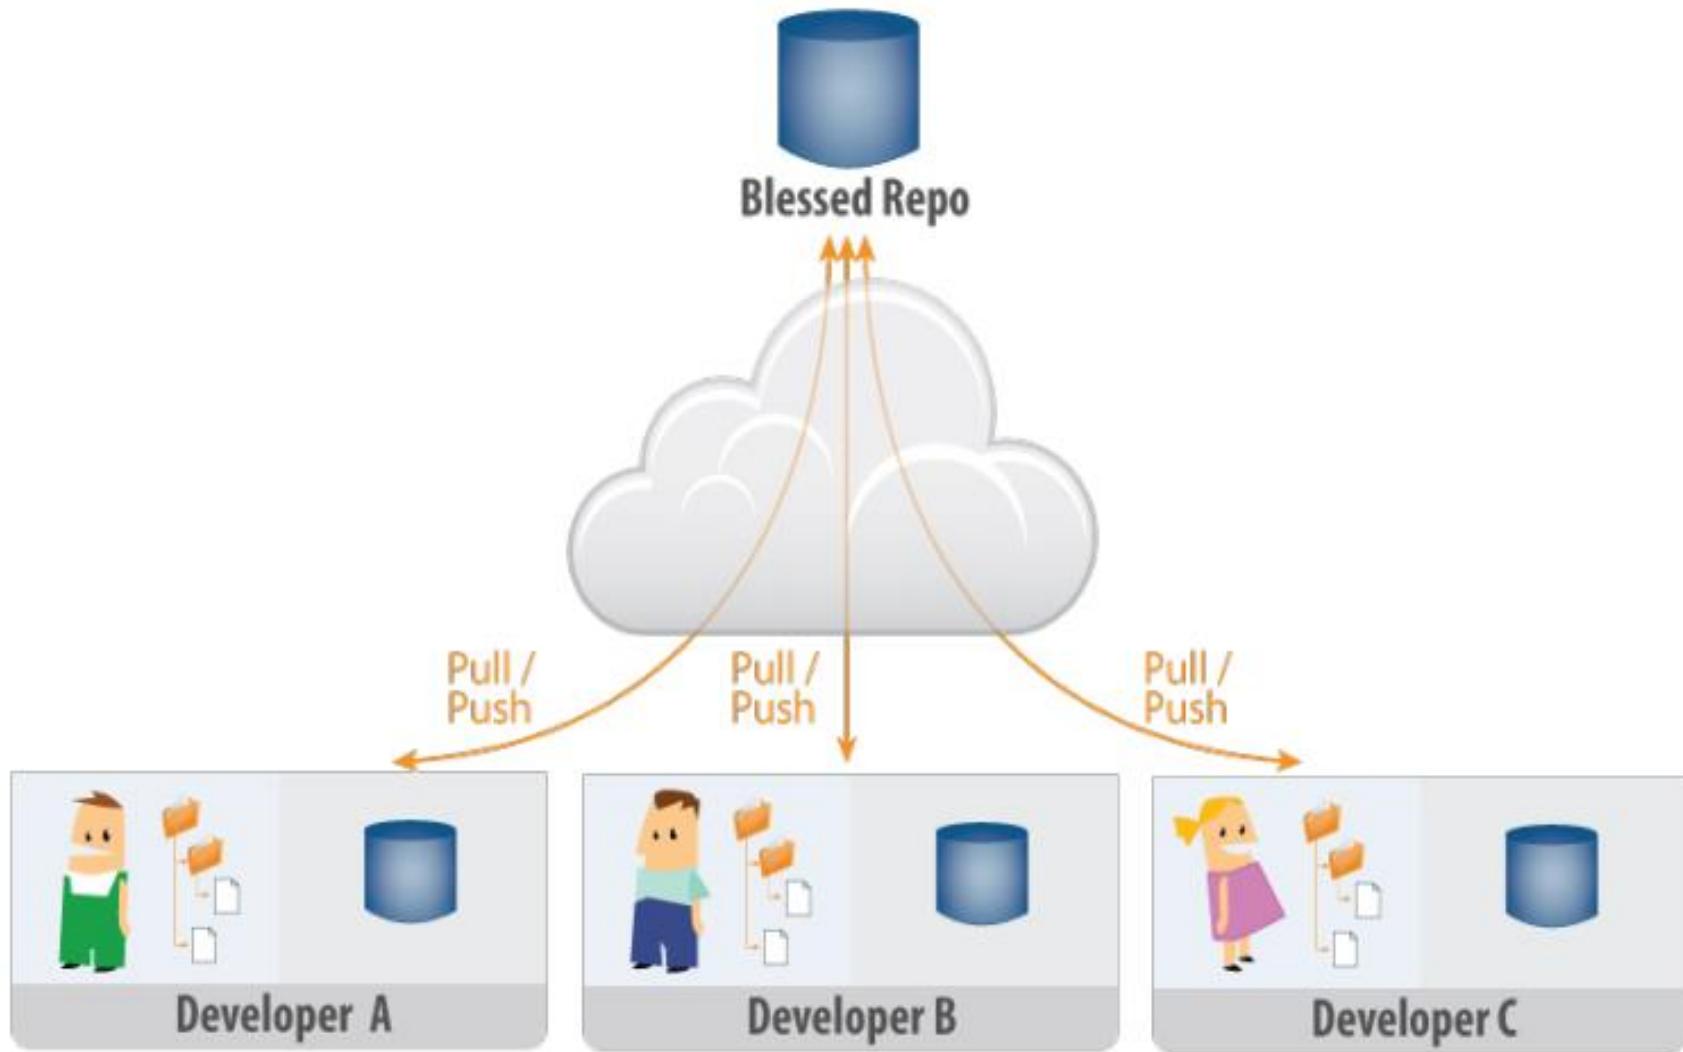

- Format patch in 1 repository, and apply it in another repository
- We will create 2 local commits squash them to 1 commit by interactive rebase, and push only 1 commit to the remote repository
- Create a commit in 1 repository and pull it from another repository, without pushing it to the origin repository

Question?

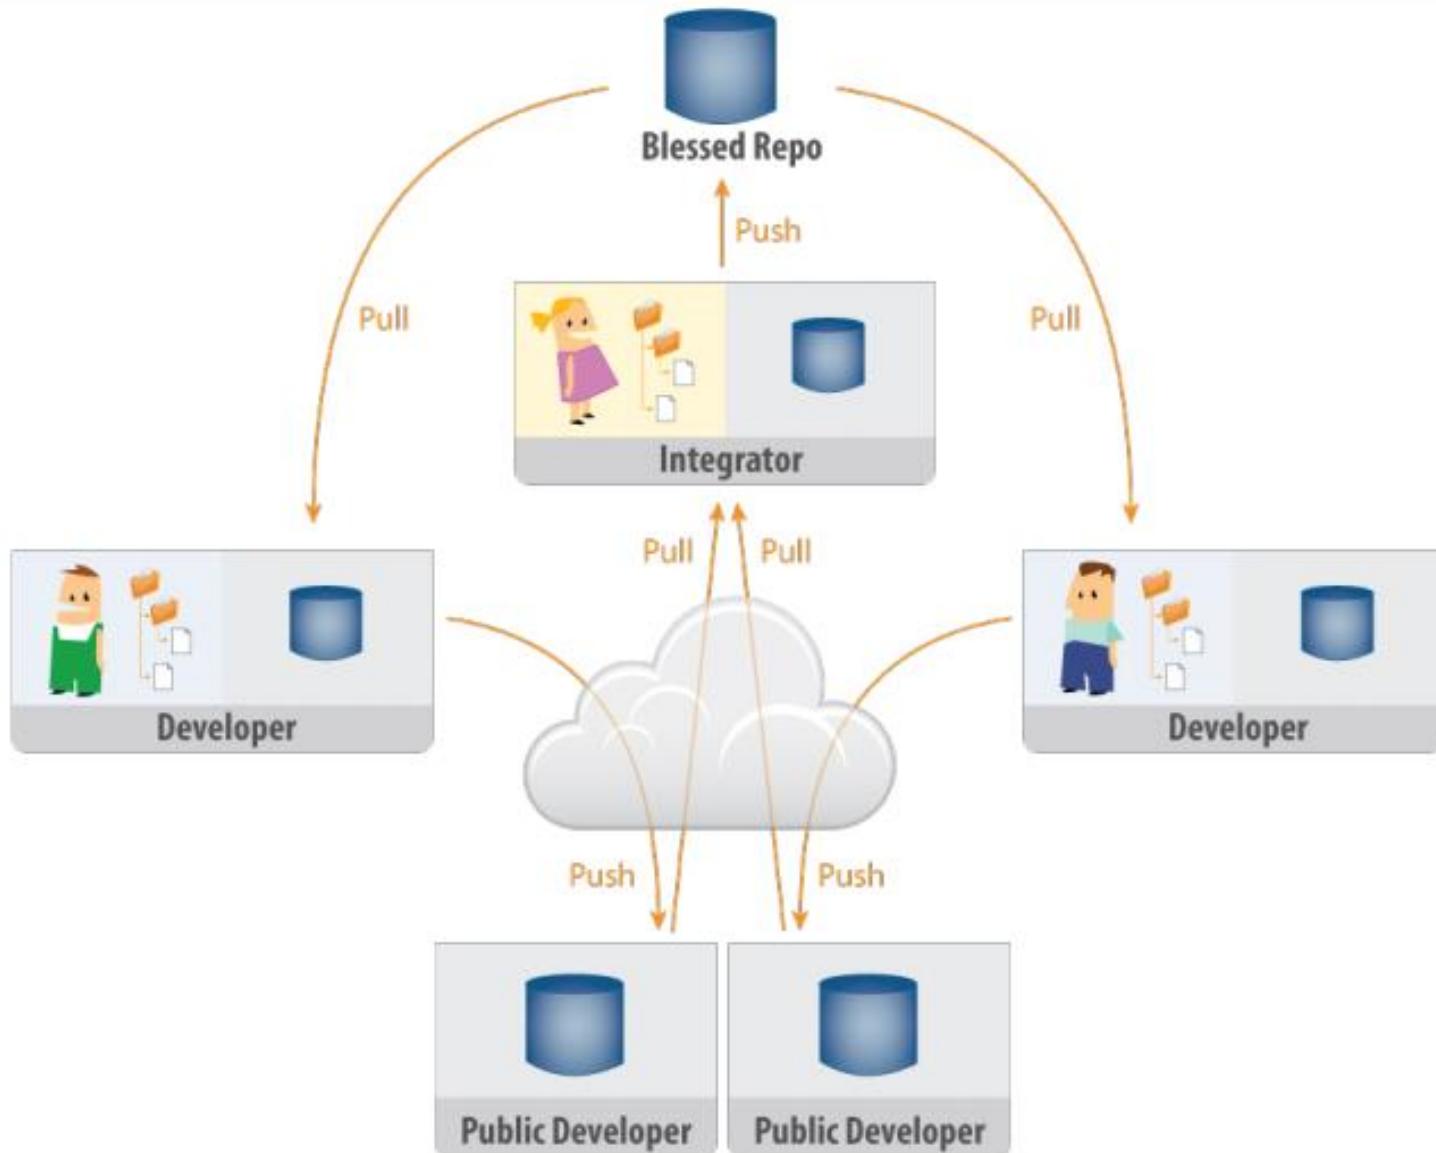

Thanks!

# Backup slides

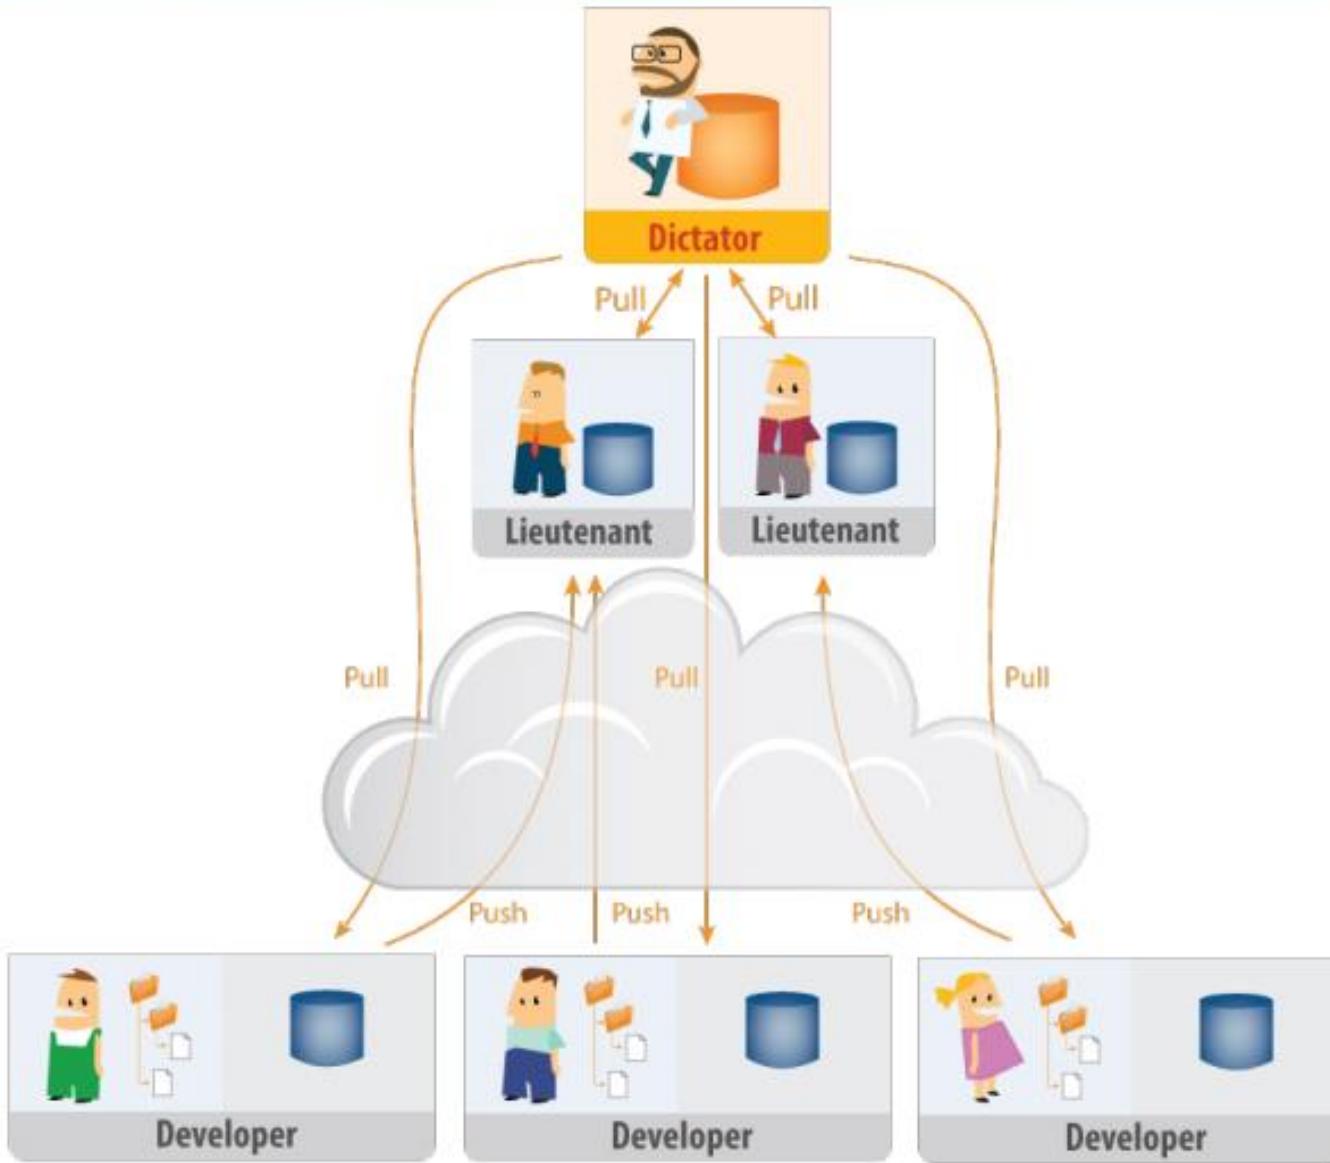

# Centralized Workflow

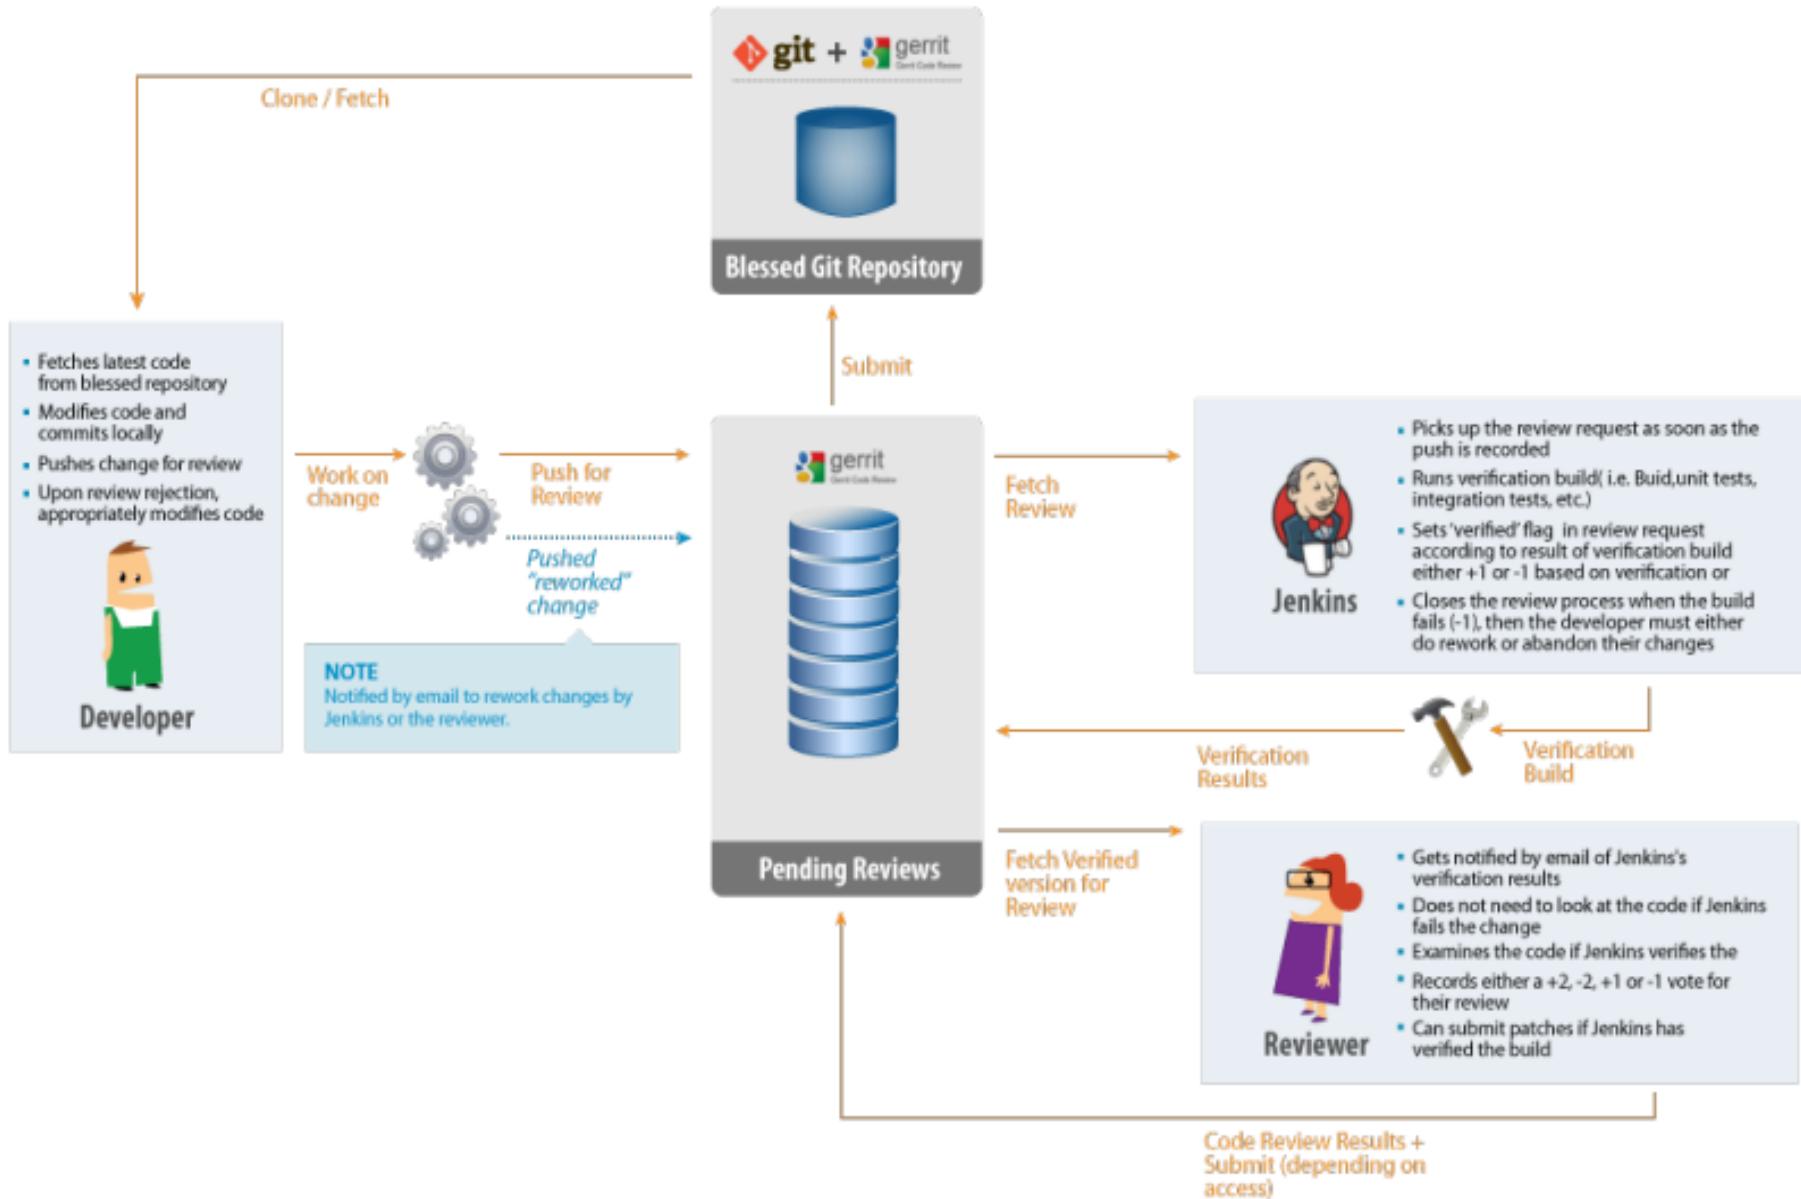

# Integrators Workflow

# Dictator / Lieutenants Workflow

# Gerrit Code Review Workflow

# Detached HEAD

If you checkout any commit SHA1, tag, or remote-tracking branch then you will end up having a “detached HEAD”:

```
$ git checkout 494e2cb73ed6424b27f9766bf8a2cb29770ale7e  
Note: checking out '494e2cb73ed6424b27f9766bf8a2cb29770ale7e'.
```

You are in 'detached HEAD' state. You can look around, make experimental changes and commit them, and you can discard any commits you make in this state without impacting any branches by performing another checkout.

If you want to create a new branch to retain commits you create, you may do so (now or later) by using -b with the checkout command again. Example:

```
git checkout -b new_branch_name
```

```
HEAD is now at 494e2cb... Added README file
```

# Git stash

You may be in a state where you have some changes that are not ready for committing, but you need to change branches in order to work on something else.

```
sheta@SHETA-THINK ~/my-project (fix-off-by-one)
$ git status
# On branch fix-off-by-one
# Changes to be committed:
#   (use "git reset HEAD <file>..." to unstage)
#
#       modified:   README.txt

$ git checkout master
error: Your local changes to the following files would be overwritten by checkout

      README.txt
Please, commit your changes or stash them before you can switch branches.
Aborting
```

**git stash** takes current state of your working directory (what is staged, modified, etc.) and saves it as a stack of unfinished changes in **refs/stash**.

```
$ git stash save --all
Saved working directory and index state WIP on fix-off-by-one: ef2f6c3 Release r
e added
HEAD is now at ef2f6c3 Release note added
```

Later you can switch back to the previous branch and apply your saved changes to your working tree to have it exactly the way you had it prior to stashing your changes. You should

# What are tracking and remote-tracking branches?

- The combination of these branches defines a relationship between a local branch and one in the remote repository.
- When a repository is cloned, Git automatically creates **remote-tracking branches** (e.g., origin/master) for the remote branches and a **tracking branch** (e.g., master) to allow for local changes in relationship to the remote branch
