

Git General Training

Git Best practices

Git manage AI tips

Deep inspection of basic commands

Ilya Rokhkin

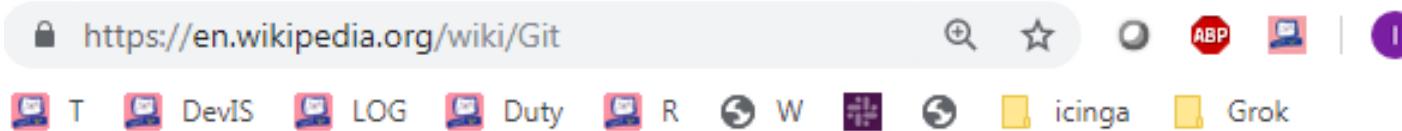

Git – meaning?

What does the word Git mean?

GIT Overview

The screenshot shows a Wikipedia page titled "Git (slang)". The page header includes the Wikipedia logo, a "Talk" tab (which is selected), and "Read" and "Edit" buttons. Below the header, the title "Git (slang)" is displayed in large, bold, serif font. A subtitle "From Wikipedia, the free encyclopedia" follows. The main content starts with a definition: "Git is a term of insult with origins in English denoting an unpleasant, silly, incompetent, ...". The page also features a sidebar with links like "Main page", "Random page", and "Recent changes".

Naming [edit]

Torvalds quipped about the name *git* (which means *unpleasant person* in [British English](#) slang): "I'm an egotistical bastard, and I name all my projects after myself. First 'Linux', now 'git'."^{[23][24]}

The [man page](#) describes Git as "the stupid content tracker".^[25]

Agenda:

1. Basic concepts and commands

- Git Architecture, data model
- DVCS, Repository, Commit, Parent Commit, Tree, Blob, Index.
- Staged, Modified, and Committed files.
- Basic commands to work in the Repository and outside.
- Sharing work with peers.
- Best practices
- How to manage AI changes in Git

2. Practical part, lab work

GIT Overview

- Quick and efficient
- Expedite distributed development
- Atomic transactions, commit, cross repository
- Commits (Change) management
- A clear internal design
- Suited to handle everything from small to very large projects with speed and efficiency
- Support and encourage branched development

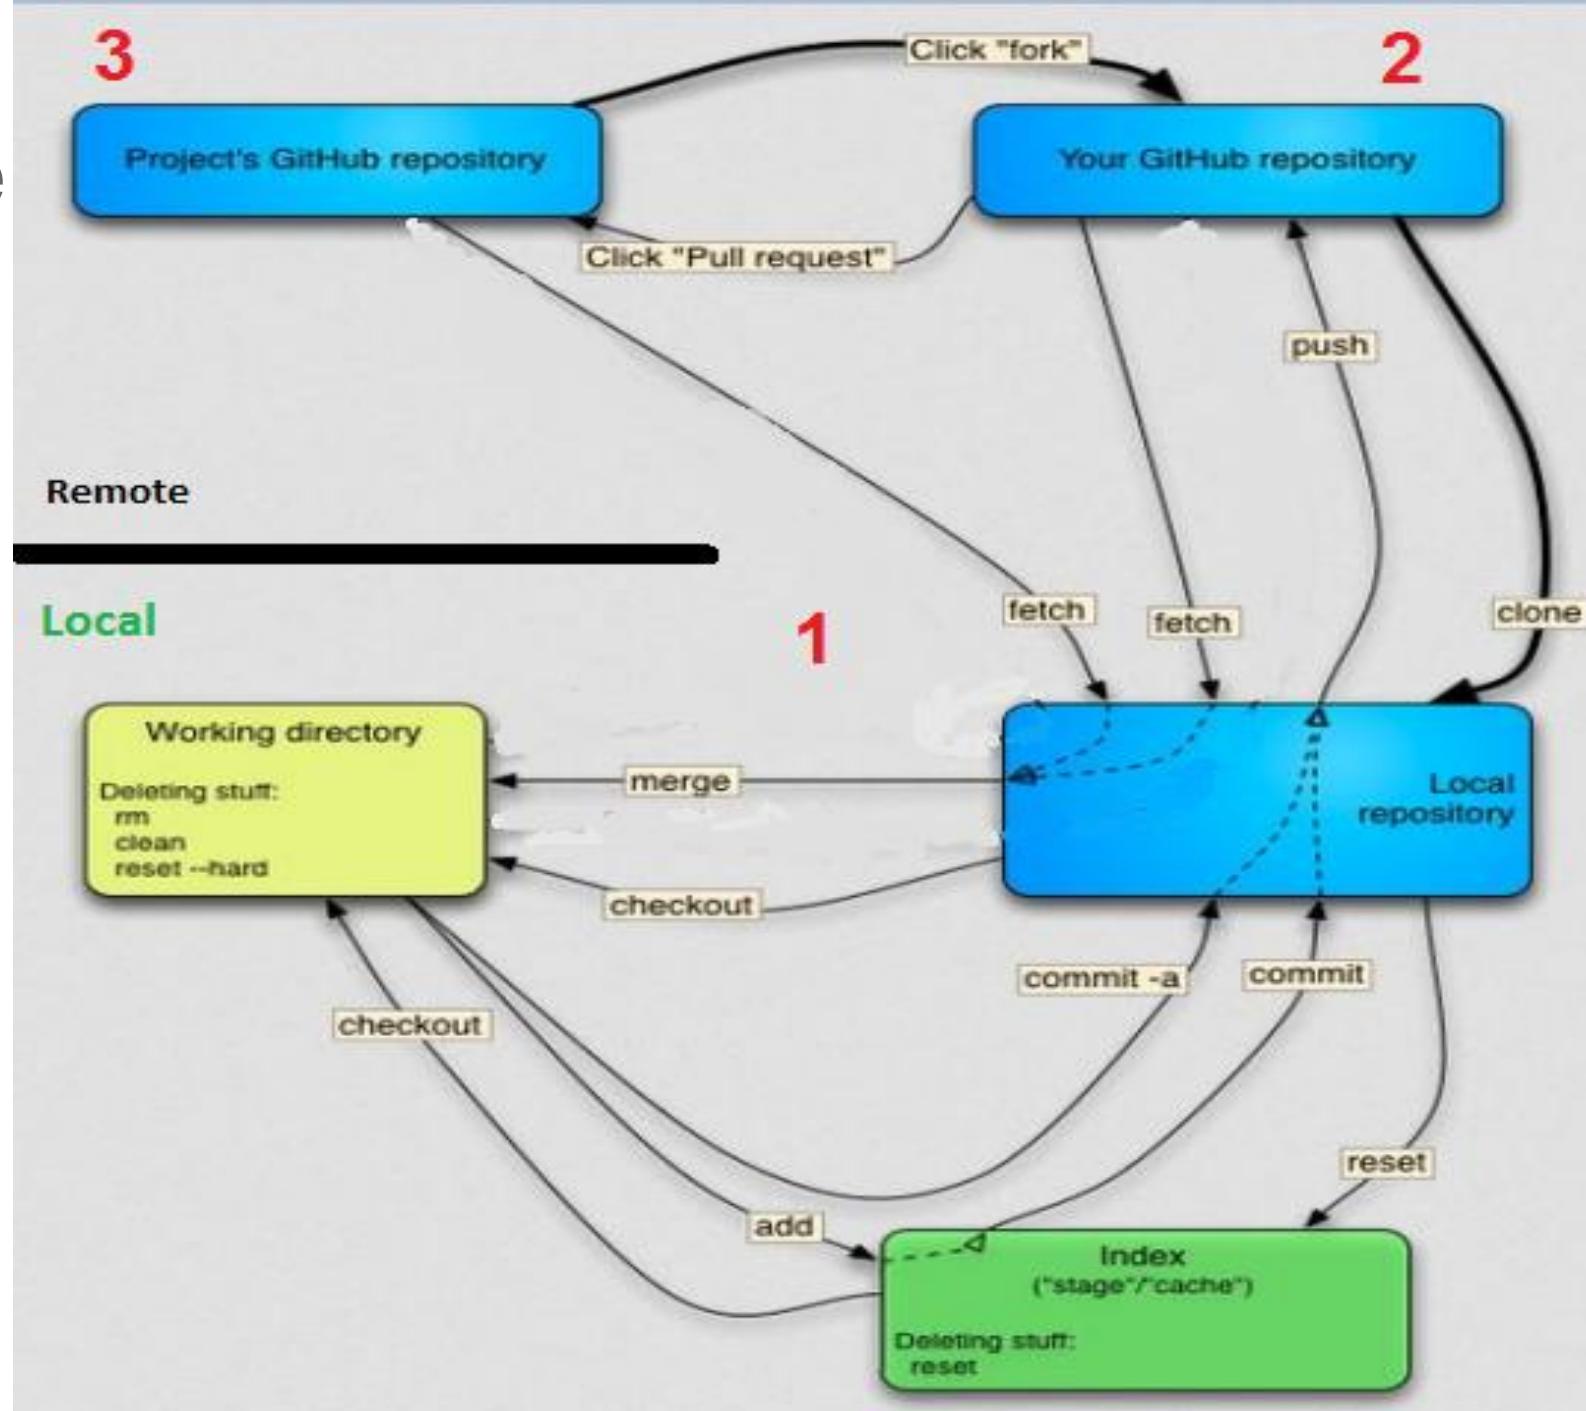

About myself:

- + Author: Ilya Rokhkin
- + Role: DevOps Engineer @ CloudOps Group
- Role: Harmony Connect DevOps
- +
+ Experience:
 - + 20+ years in VCS
 - + Git trainer (CHKP,
Freelancer)
 - (Intel, Marvell)
 - + Hebrew teacher
volunteer @ Ulpan

GIT Architecture

- 1 Local repo
- 2 Remote
(Origin)
- 3 Common
(Community)
Remote
Origin

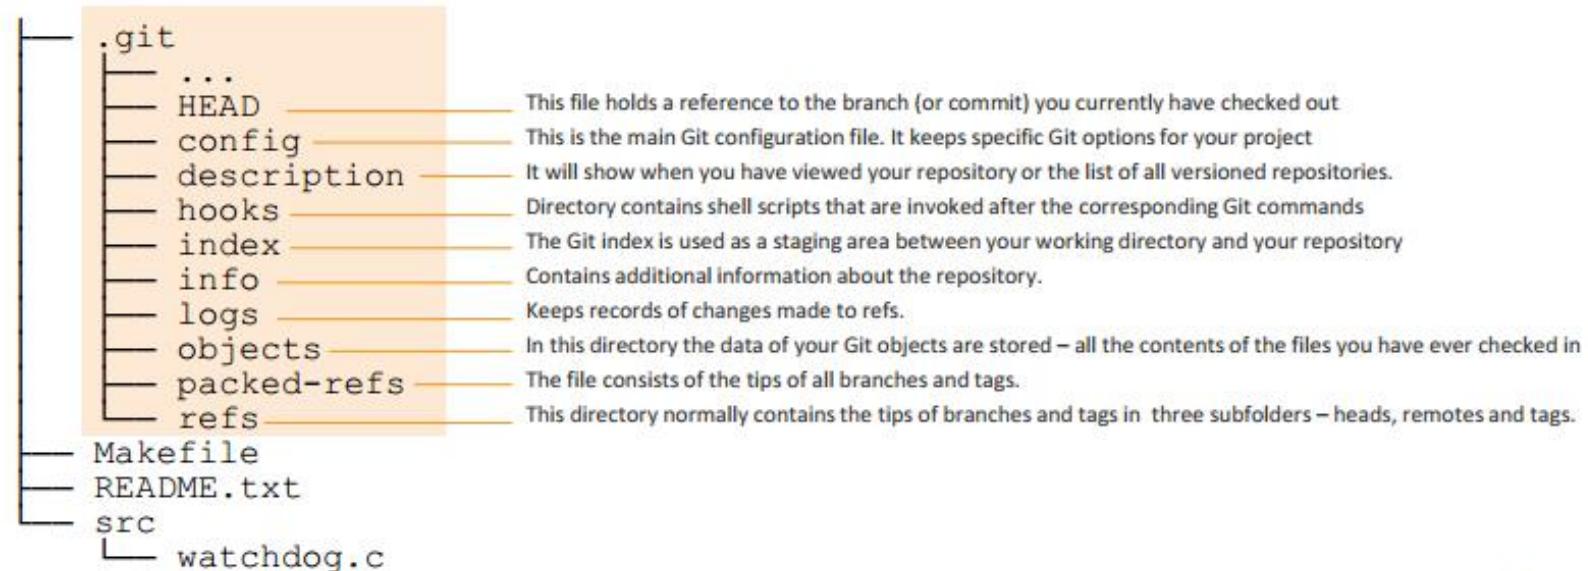

Demo

Lab 1 - 2

- We will configure your git user and e-mail
 - Will create a remote, bare repository in the home directory
 - Clone it to work repository1 in the home directory also, add, commit, and push
 - Restructure files, add, commit, and push

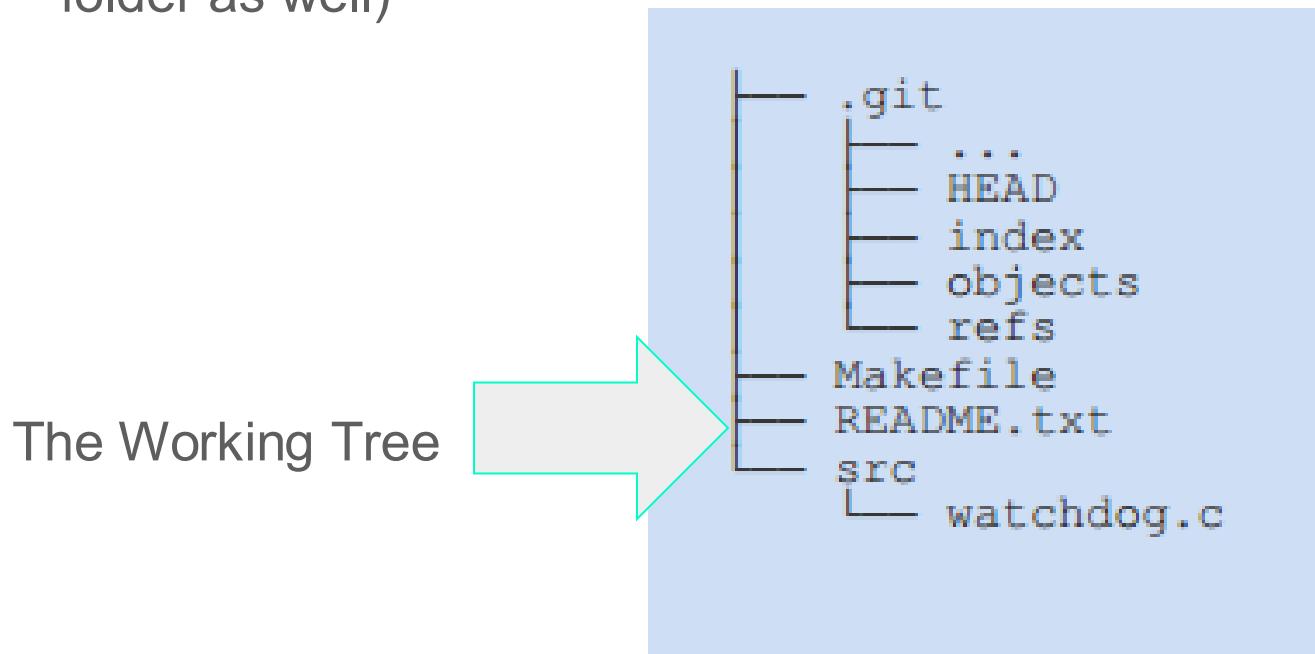

Git repository structure (.git)

```
$ ls -al
total 11
drwxr-xr-x  7 sheta  Administ  4096 Dec  3 15:17 .
drwxr-xr-x  3 sheta  Administ  4096 Nov 30 11:26 ..
-rw-r--r--  1 sheta  Administ   23 Nov 30 11:09 HEAD
-rw-r--r--  1 sheta  Administ  363 Nov 30 11:46 config
-rw-r--r--  1 sheta  Administ   73 Nov 29 17:03 description
drwxr-xr-x  2 sheta  Administ  4096 Nov 29 17:03 hooks
-rw-r--r--  1 sheta  Administ  32 Nov 30 11:26 index
drwxr-xr-x  2 sheta  Administ     0 Nov 29 17:03 info
drwxr-xr-x  3 sheta  Administ     0 Nov 29 17:03 logs
drwxr-xr-x 25 sheta  Administ  4096 Nov 30 11:08 objects
-rw-r--r--  1 sheta  Administ  94 Nov 29 17:03 packed-refs
drwxr-xr-x  5 sheta  Administ     0 Nov 30 11:07 refs
```

The Working Tree

- The working tree has all files and folders as found in your HEAD, plus the changes you made since your last commit
- There is only ONE main working tree per repository (and only 1 .git folder as well)

States of files in Working Tree

- **Untracked** – in the repository folder, git does not keep a version of it.
- **Modified** – tracked, modified since last stage or commit.
- **Staged** – a snapshot of the file, ready to be committed. Even if modified, git will still keep the snapshot.
- **Committed** – version of file saved in repository DB

Objects

Every object in GIT composed of those elements –

Type – “blob”, “tree”, “commit”, “refs” (branch/tag).

A "blob" is basically like a file – it is used to store the content of a source file.

A "tree" is basically like a directory - it references a group of other trees (subdirectories) and/or blobs (files).

A "commit" points to a single tree, marking it as what the project looked like at a certain point in time. Keeps changed files since the last commit, author of the changes, a reference to the parent commit(s), etc.

A “refs” is a way to mark a specific commit as special in some way. It is usually used to tag certain commits as specific releases or something along those lines.

Objects cont.

Almost all the GIT is built around manipulating this simple structure of four different object types. It is sort of it's own little file system that sits on top of your machine's file system.

Let's say we have a small project that looks like this:

```
$>tree  
.  
|-- README  
`-- lib  
    |-- inc  
    |   '-- tricks.rb  
    '-- mylib.rb  
  
2 directories, 3 files
```

If we will commit this project to a GIT repository, it will be represented in GIT like this:

Commit Object

98ca9..

commit	size
tree	0de24
parent	nil
author	Scott
committer	Scott
my commit message goes here and it is really, really cool	

0de24..

tree	size
blob	e8455
README	
tree	10af9
lib	

e8455..

blob	size
== LICENSE:

tricks.rb	

0ad1a..

blob	size
require 'grit/git-ruby/repository'	
require 'grit/git-ruby/file_index'	
module Grit	
module Tricks	

Commit object with its parent

- Links from tree object to common blobs

Secure Hash Algorithm – SHA1

- Each object in Git is represented by a 40-digit string that resembles this:
7bf68ebf3d8cff042bd3cb87e7592ddda9caa665.
This string is being calculated by taking the SHA1 hash of the contents of the object.

Each commit has
Author and
Committer

The Author is who
really wrote the code,
and committed

Committer, if not the
same as the Author,
took Original commit
and reused it in his
branch

```
MINGW32:/c/Users/Ilya/sally1
Ilya@Ilya-THINK MINGW32 ~/sally1 (master1)
$ git log --pretty=fuller --stat
commit c3dd67d83ce90b75b9d94af5a357eb37a34d80db (HEAD -> master1)
Author:    ilya <astra07_2010@yahoo.com>
AuthorDate: Thu Jul 13 21:50:02 2017 +0300
Commit:   ilya <astra07_2010@yahoo.com>

      first harry's change

libs/library.txt | 2 ++
1 file changed, 1 insertion(+), 1 deletion(-)
```

The HEAD

- HEAD is a 'pointer' to the tip of the currently checked out branch
 - In a *detached HEAD* state, HEAD points directly to a commit
- Only one HEAD per repository

Demo

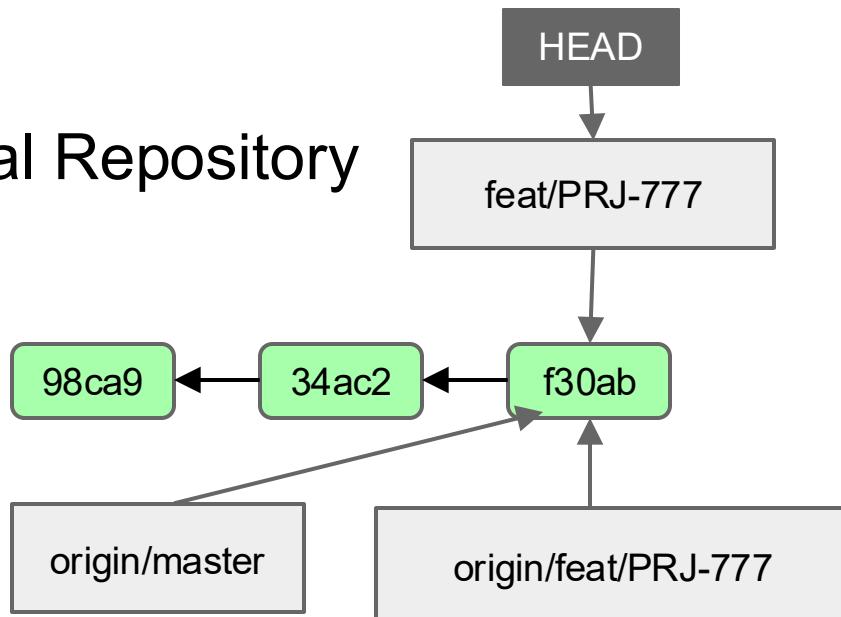

Lab 3

Teamwork, parallel work:

- We will clone the second work repository2
- We will commit changes in both repositories
- Push and pull with silent rebase to apply the commit of one repo into another
- Overview results

Rebasing Remote Tracking Branch

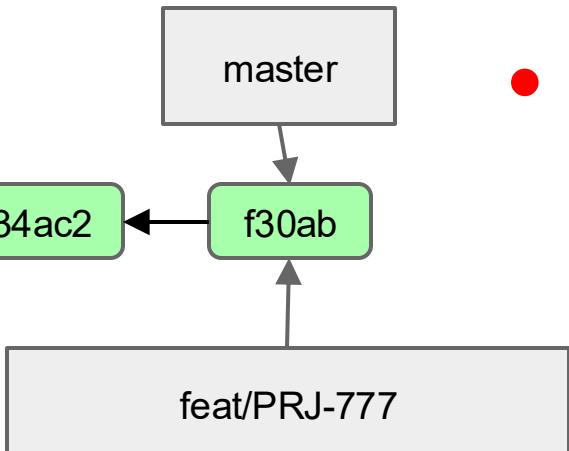

Local Repository

Tracking Branch (Local)

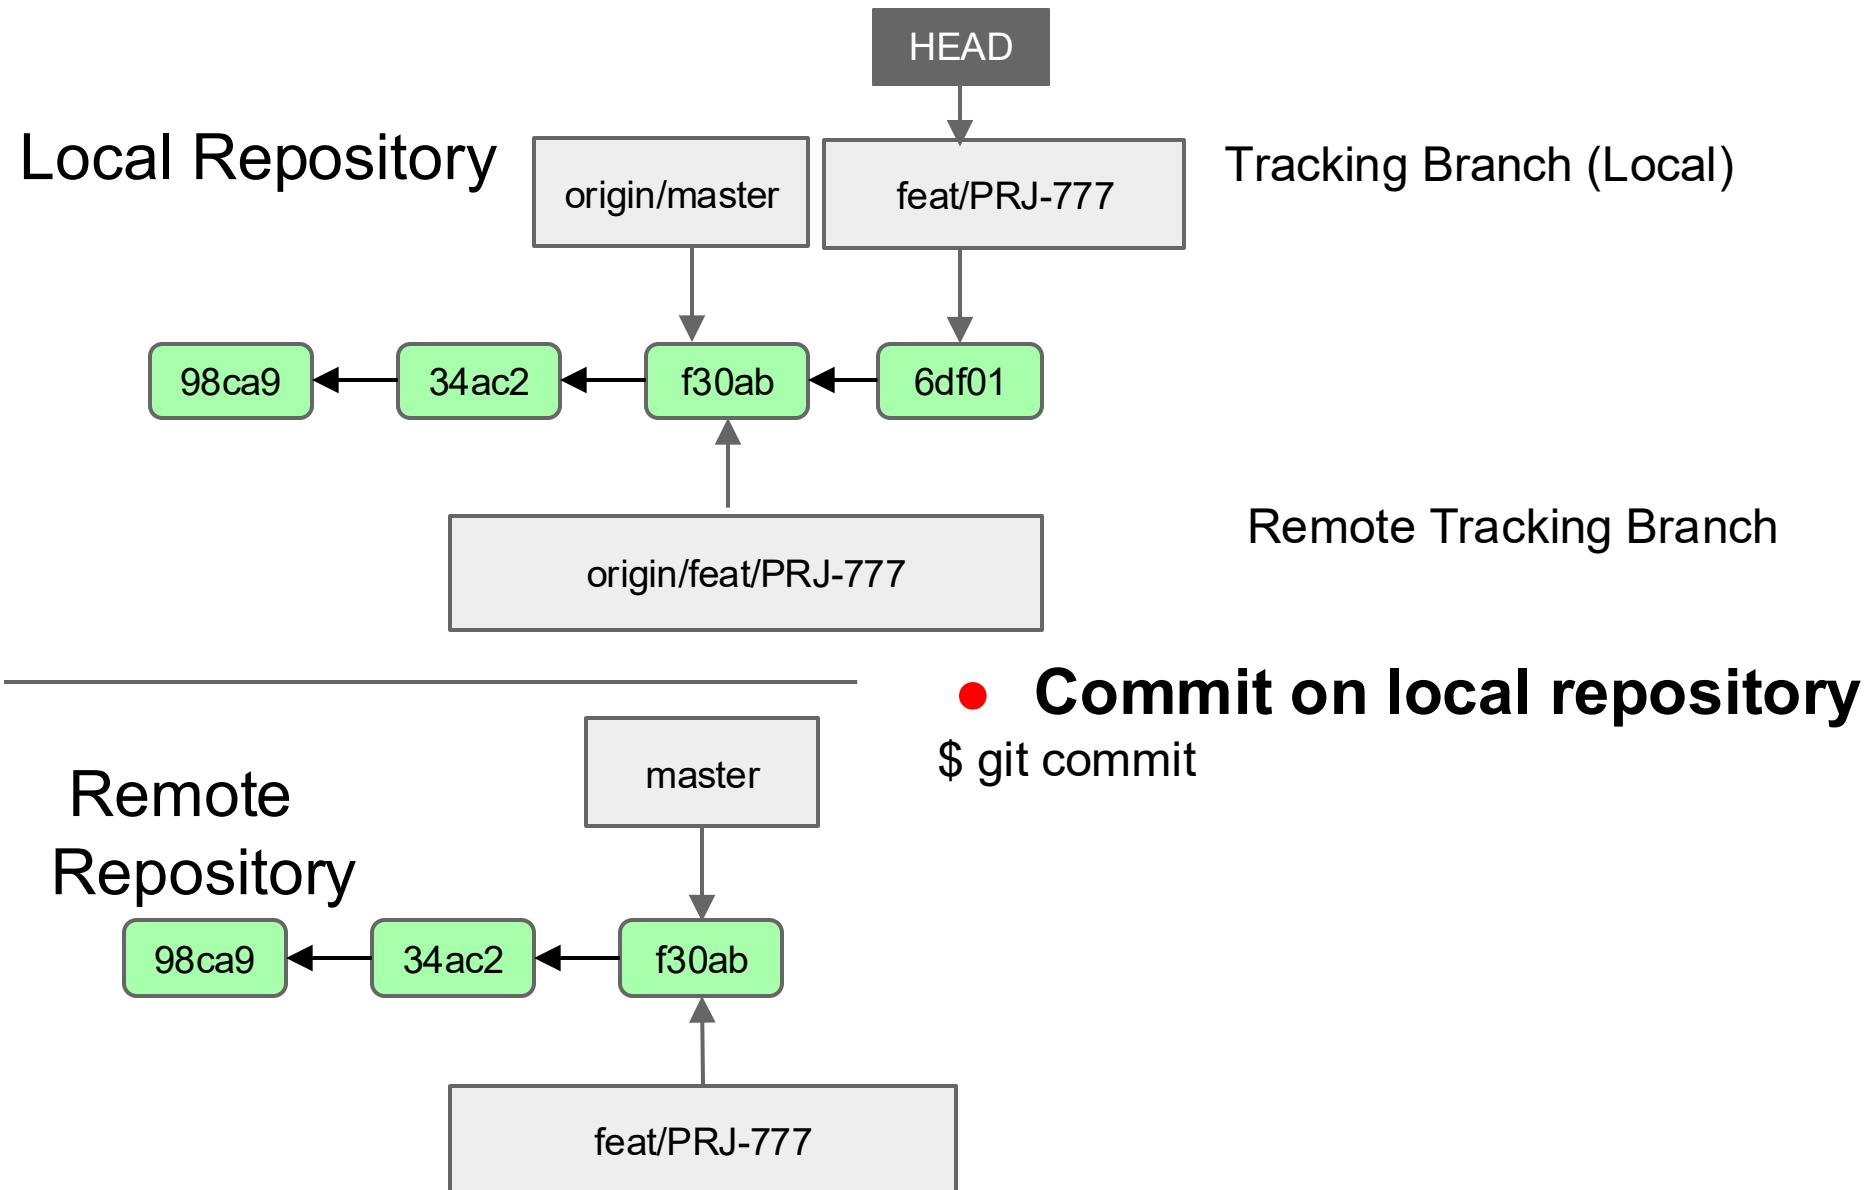

Remote Tracking Branch

Remote
Repository

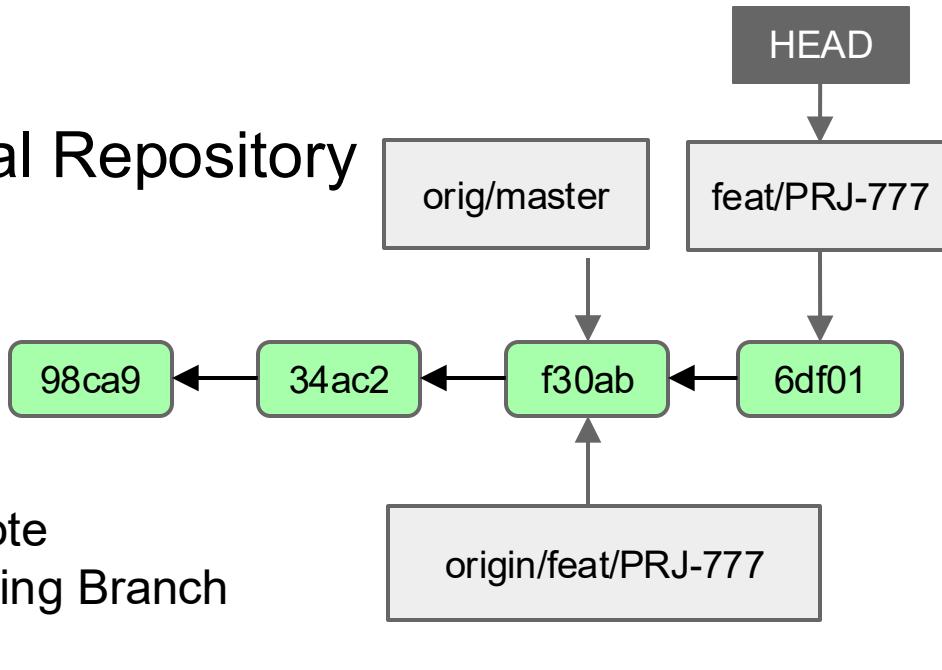

- After clone/pull Remote Tracking Branch and Tracking (Local) branch pointing to the same commit

Rebasing Remote Tracking Branch

Remote Repository

Applying: diff/patch of commit 6dfo on top of origin/master to create commit 3f9f9

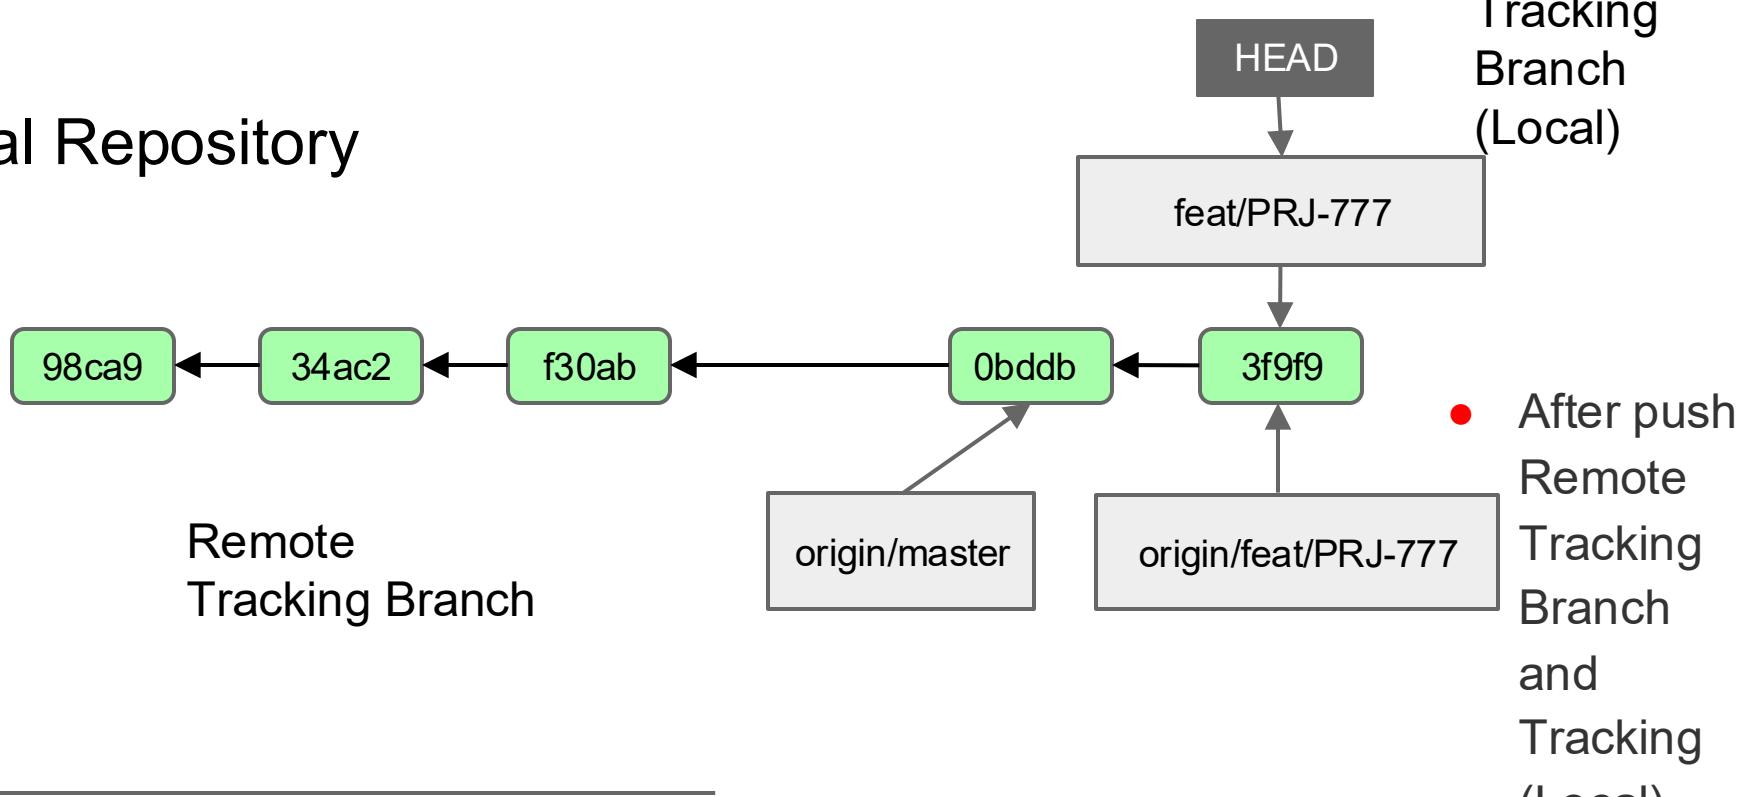

Rebasing Remote Tracking Branch

Local Repository

Rebasing Remote Tracking Branch

Local Repository

Remote Repository

Perils of rebase

- **Do not rebase commits that you have pushed to a public repository.**

If you follow that guideline, you'll be fine. If you don't, people will hate you, and you'll be scorned by friends and family.

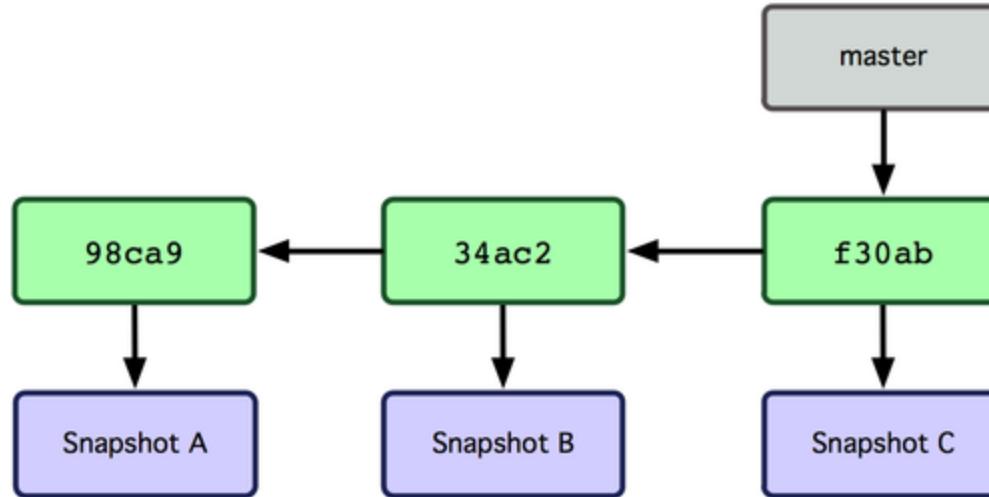

Demo

Lab 4

- Teamwork, parallel work with rebase, and conflict resolution:
- We will do commits in both repositories, with changes in the same line of the same file
- Pull with rebase, resolve conflicts, and save the resolution file
- Adding the file to the staging area means resolving the issue.
- Commit and push

Git branches

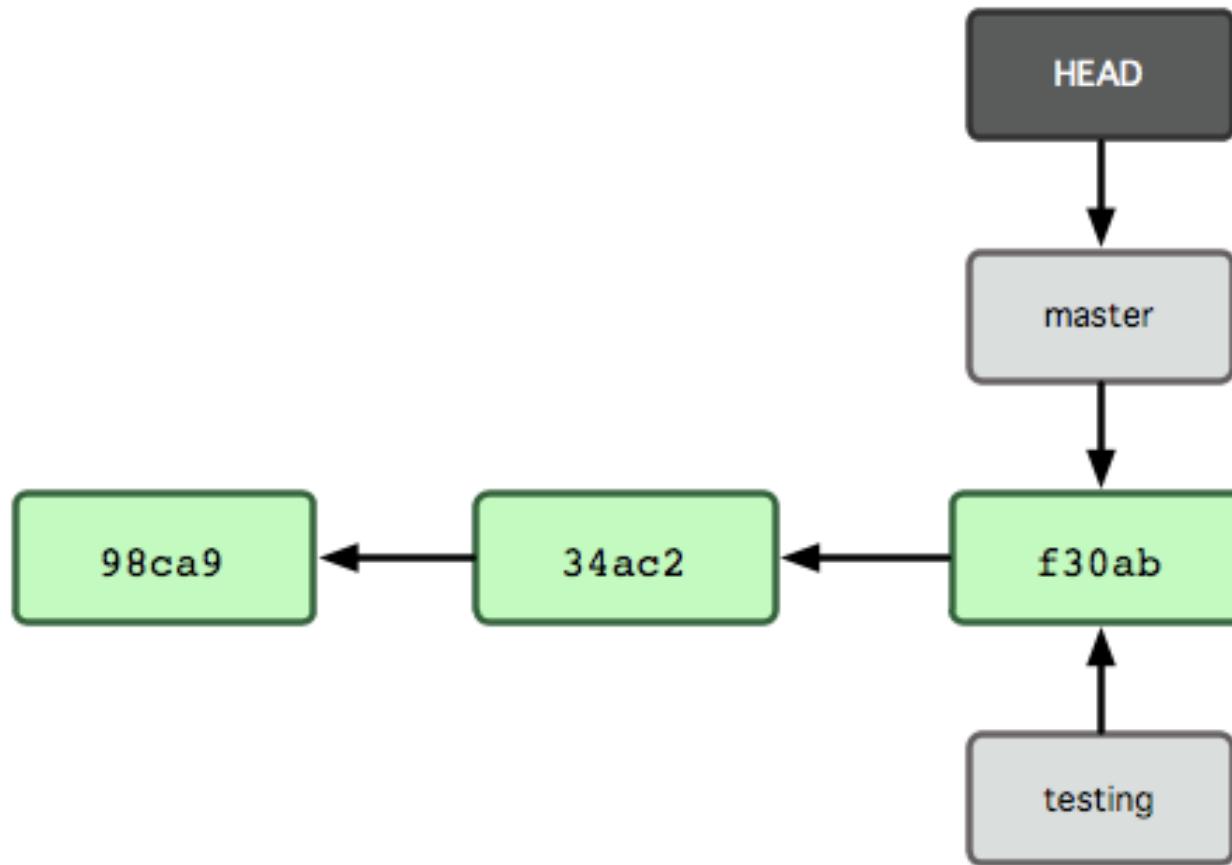

- Git branch is simply a movable pointer to a commit

- Pointer moves forward automatically with each commit on a branch

Creating new branch

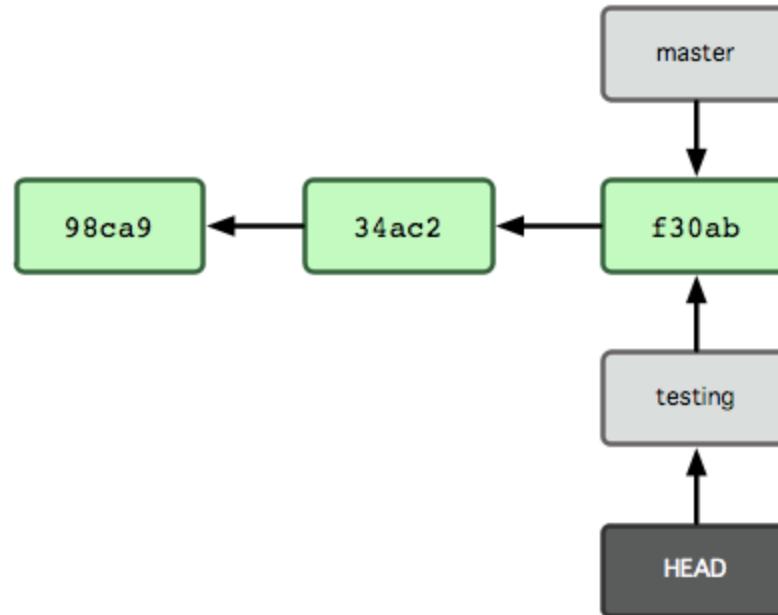

- New branch creates a new reference
`> git branch testing`

Switching to a branch

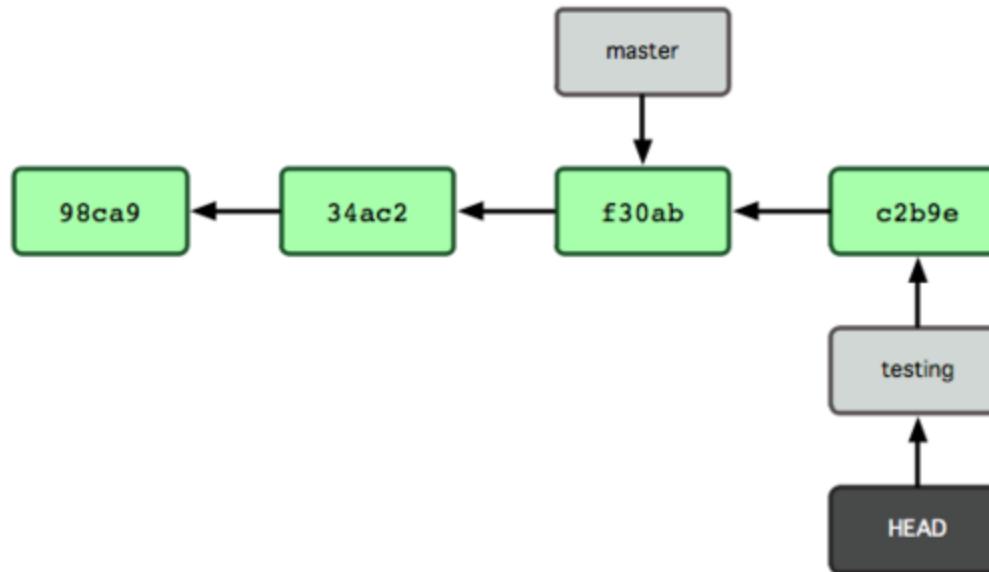

- Git checkout *branch-name* switches to an existing branch

```
> git checkout testing
```

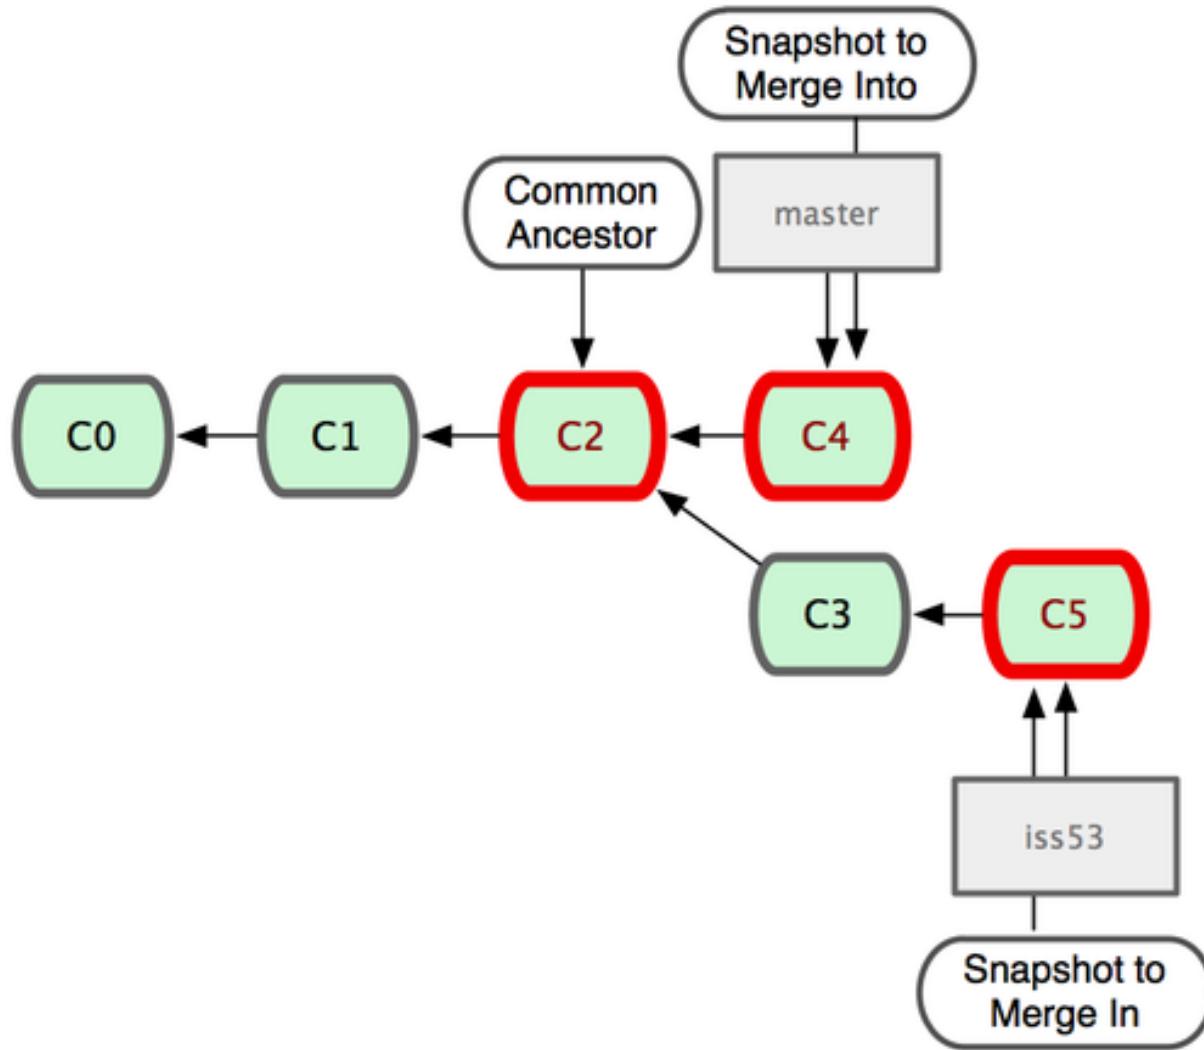

New commit moves current branch

```
> vi file04.txt  
> git commit -a -m 'Commit message'
```

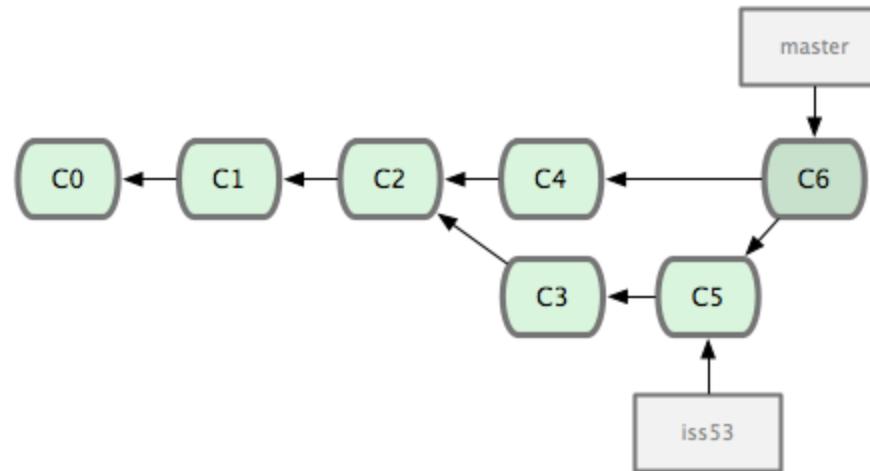

Merging branches

Merging branches (continued)

- As a result of merge Git creates a new commit, which has two parents:

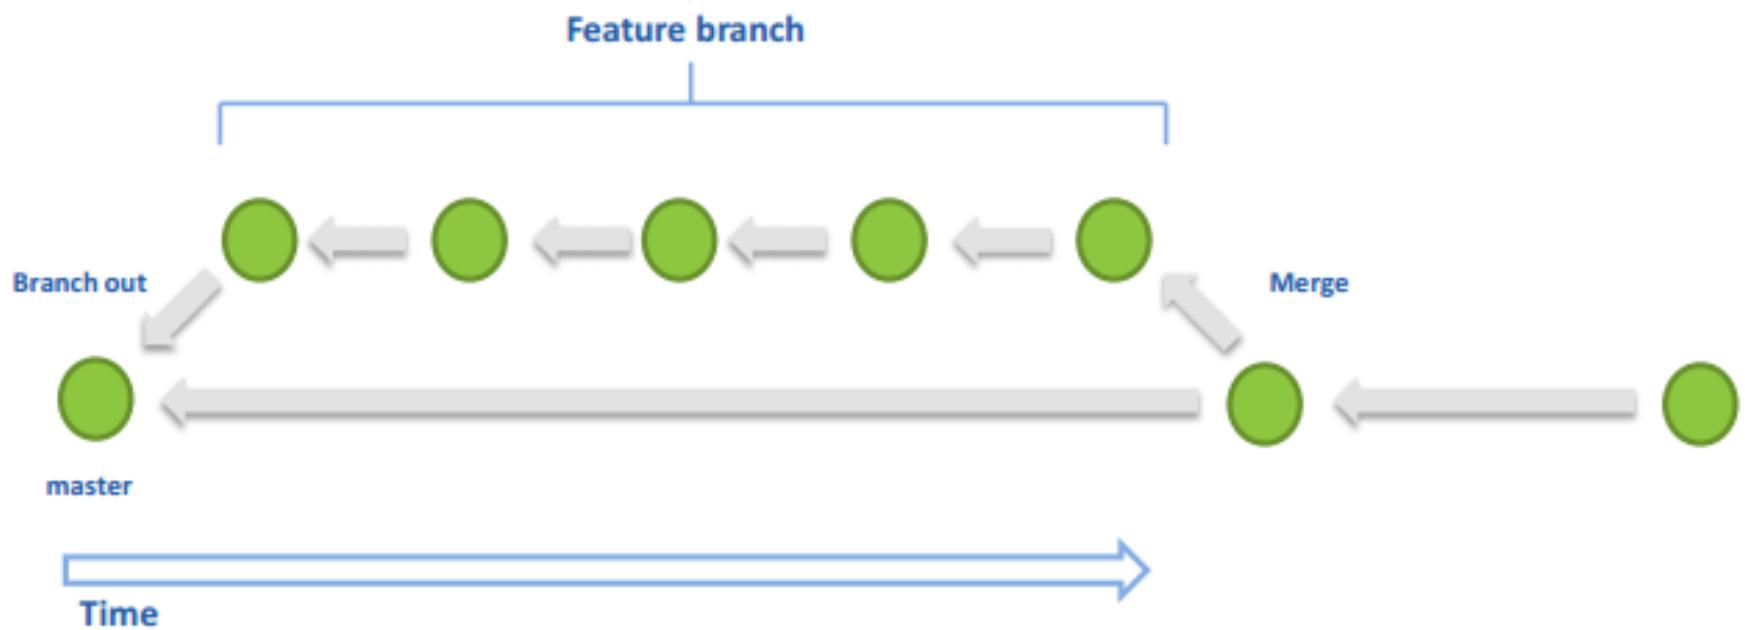

Demo

Lab 5 - 7

- We will create a tag
 - Create branch bugfix from the tag
 - I will do a bugfix commit in the bugfix branch
 - Check out the master branch and commit a new change
 - Merge bugfix branch
- Overview results

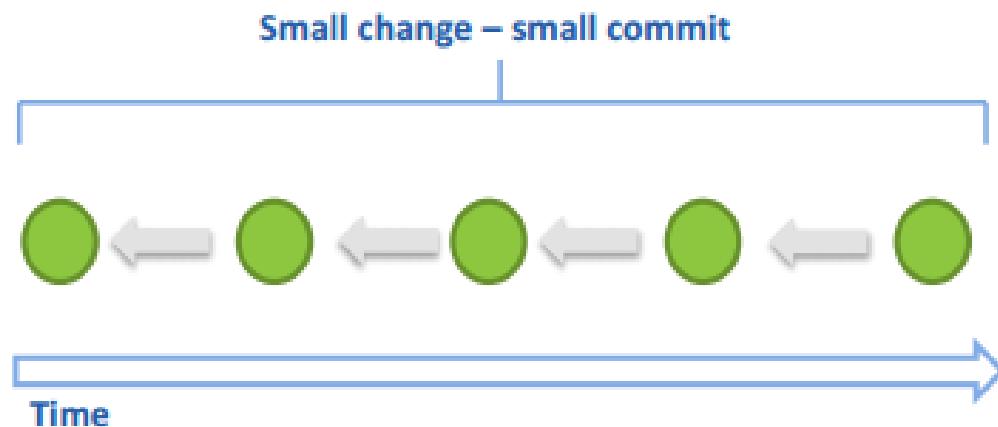

Best practices – local feature branches

Work on feature branches locally

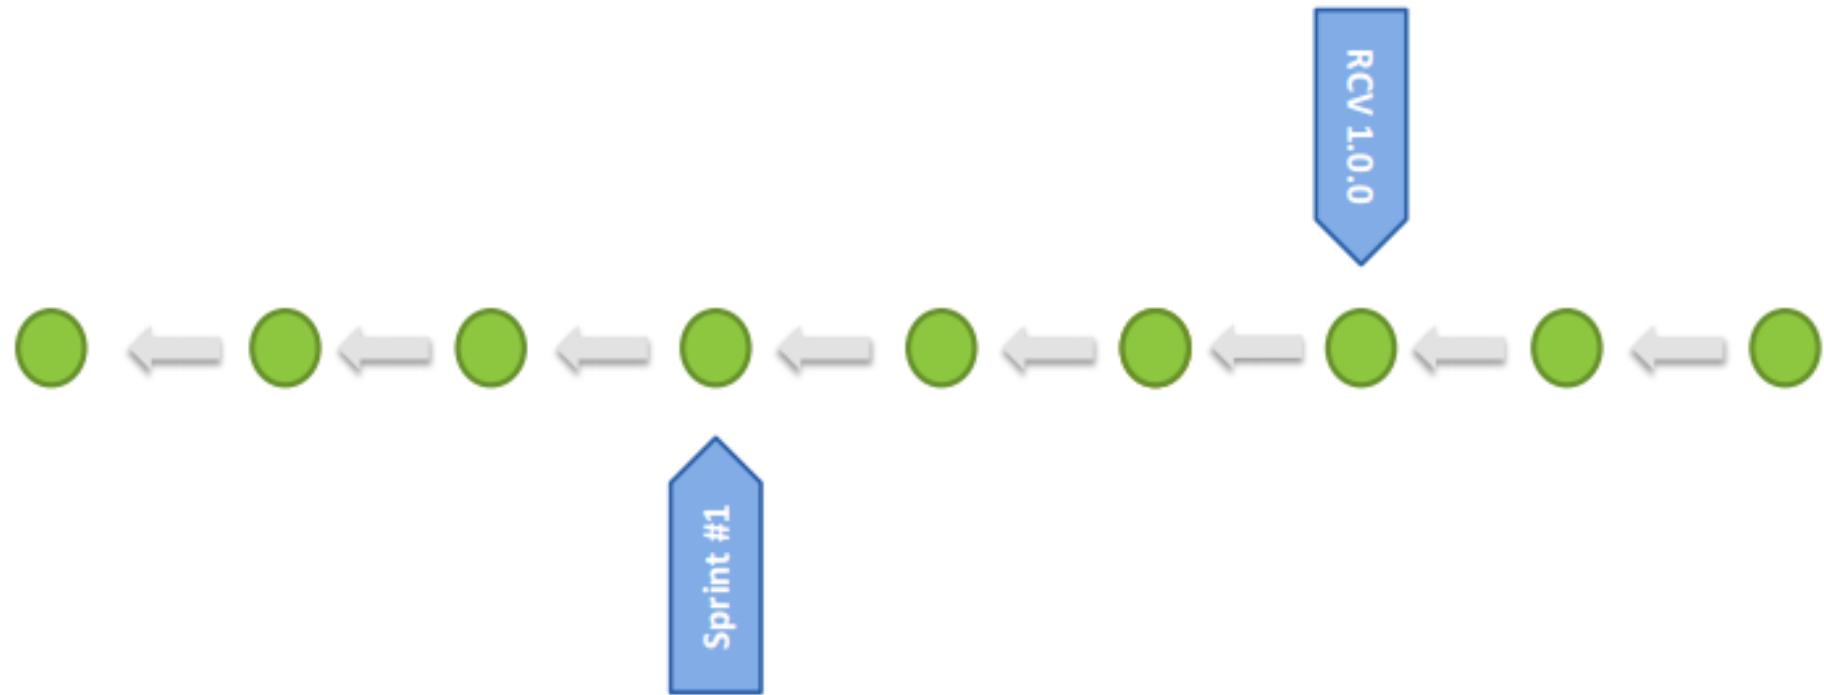

Best practices – commit

Keep changes small wherever possible and commit frequently

Best practices – tag milestones and important working changes!

Tag important milestones (for history and for accessibility)

How Git can manage AI changes

- VS Code Preferences:

Open User Settings

Control AI Changes with Auto-Commit-Push

VS Code Preferences: Open User Settings (JSON)

```
"emeraldwalk.runonsave": {
  "commands": [
    {
      "match": ".",
      "cmd": "git rev-parse --is-inside-work-tree >/dev/null 2>&1 && git ls-files --error-unmatch ${file} && git commit -m \"`git diff -U0 ${file} | tail -1`\" ${file} && git symbolic-ref --short refs/remotes/origin/HEAD | grep -v $(git branch --show-current) > /dev/null 2>&1 && git push"
    }]
},
```

Tag important working changes and push:

```
$ git tag v0.0.19 && git push  
-tags
```

- Save time for commits, keep them on the git server in a feature branch
- Reset to working tag when needed

```
$ git reset --hard v0.0.19
```

```
commit 2249f5a2a6a34575b2e81363a58d6a2d0be08576 (tag: v0.0.19)
Author: ilyaro <ilyaro@checkpoint.com>
Date:   Tue Oct 7 15:45:36 2025 +0300

        +           token: ${{ secrets.PAT_TOKEN }} # Use PAT to allow triggering other workflows

```

Rebase on top of updated origin/main branch before pushing for code review.

Do it now on your current work branch.

https://github.com/ilyaro/git_best_practices_ppt/blob/master/Git_Rebase_Best_Practices.md

Best practices – squashing

Before pushing, squash related changes together to make for better understanding by others

Best practices - concise commit messages

For manual 1, commit before opening PR/MR

Limit commit message header to **60 characters** and add the meaningful details in the rest of the message

```
commit f6ce5cc010bf6665a8f2a701e7983e0c2ac8f144  
Author: Shawn O. Pierce <sop@google.com>  
Date: Thu Nov 29 09:55:47 2012 -0800
```

Sort comments before emailing them

The order supplied by the caller can be random, ensure comments get sorted into a sane order before they are included into the email.

Bug: issue 1692

Change-Id: ibd85e514977545d022f936a5993f2a6ef6e52321

Best practices – Branch Layout

Branch layout

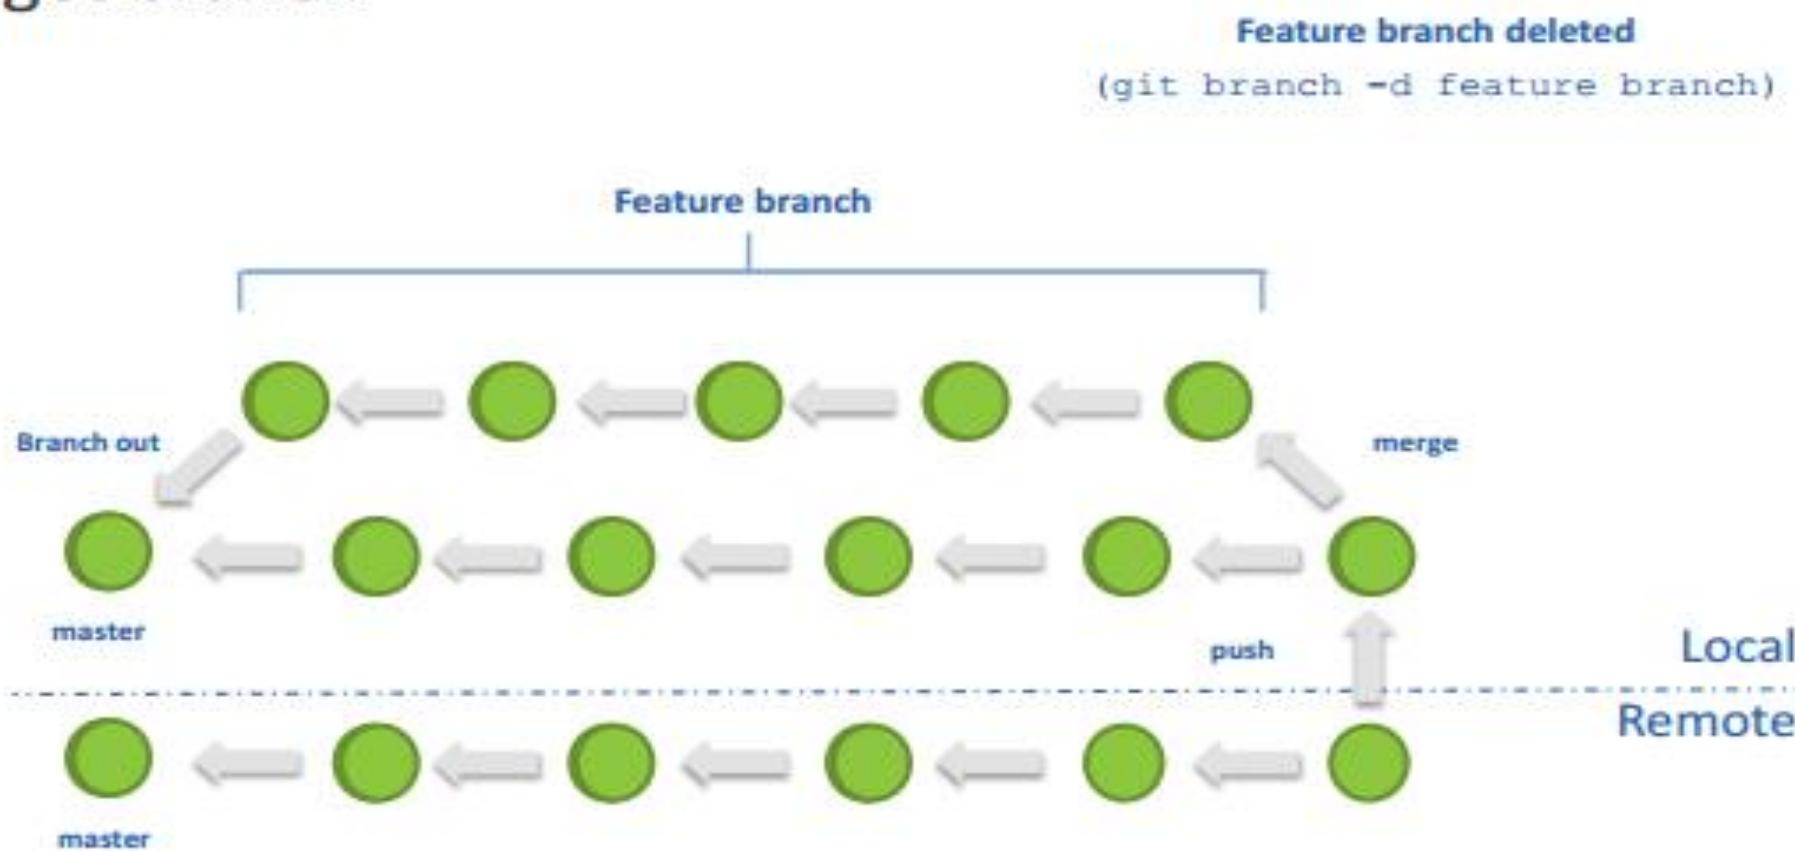

The branch layout is up to you, but there are some best practices though:

```
$ git branch # GOOD
  master
* devel
  feature/new-mailform
  fix/off-by-one
  fix/readme-grammar
```

```
$ git branch # BAD
  master
* devel
  new
  fix
  fix2
  t3rrible-br@nch-name
```

Best practices – clean up local branches

Clean up local branches once the code gets pushed to target branch

"S git branch --merged" will show all branch(es) which can be safely deleted

Lab 8 - 10

- We will create branch bugfix2, from Release_01
Cherry-pick 1 commit from the master branch
- Undo modified file, undo staged file
Undo the latest local commit, revert the pushed commit
- Stash meanwhile work aside, make a commit,
return work from stash

Lab 11 - 13

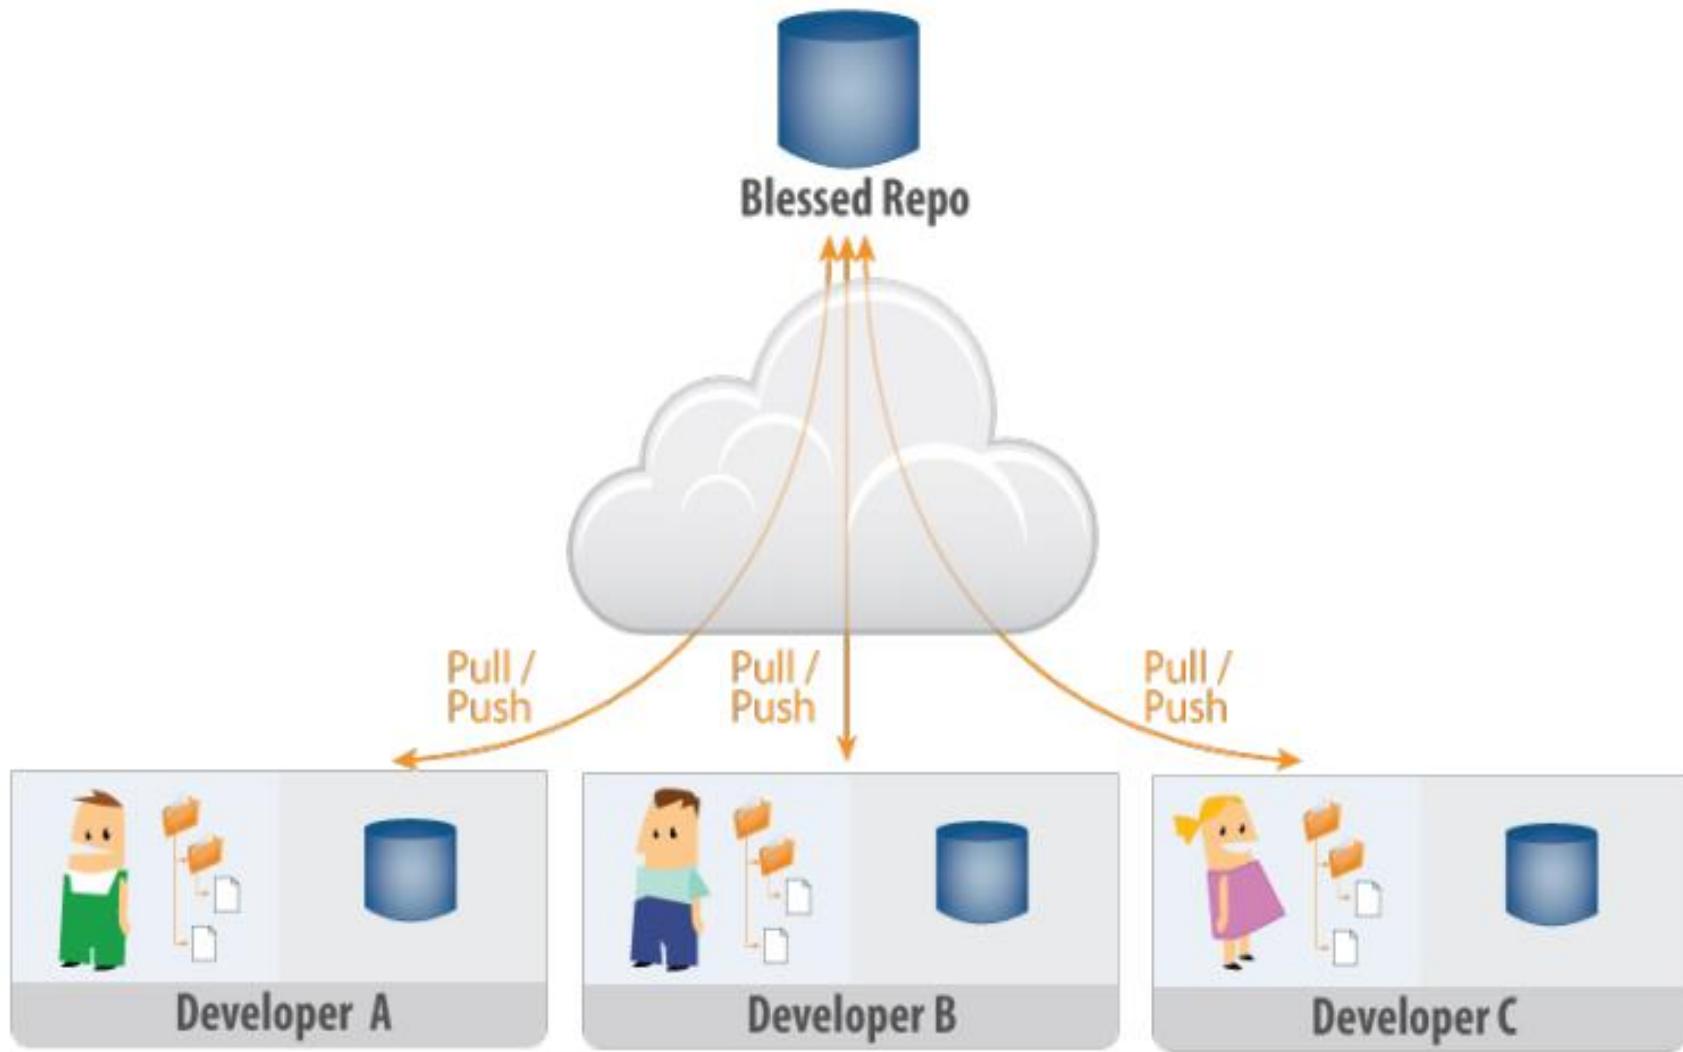

- Format patch in 1 repository, and apply it in another repository
- We will create 2 local commits squash them to 1 commit by interactive rebase, and push only 1 commit to the remote repository
- Create a commit in 1 repository and pull it from another repository, without pushing it to the origin repository

Question?

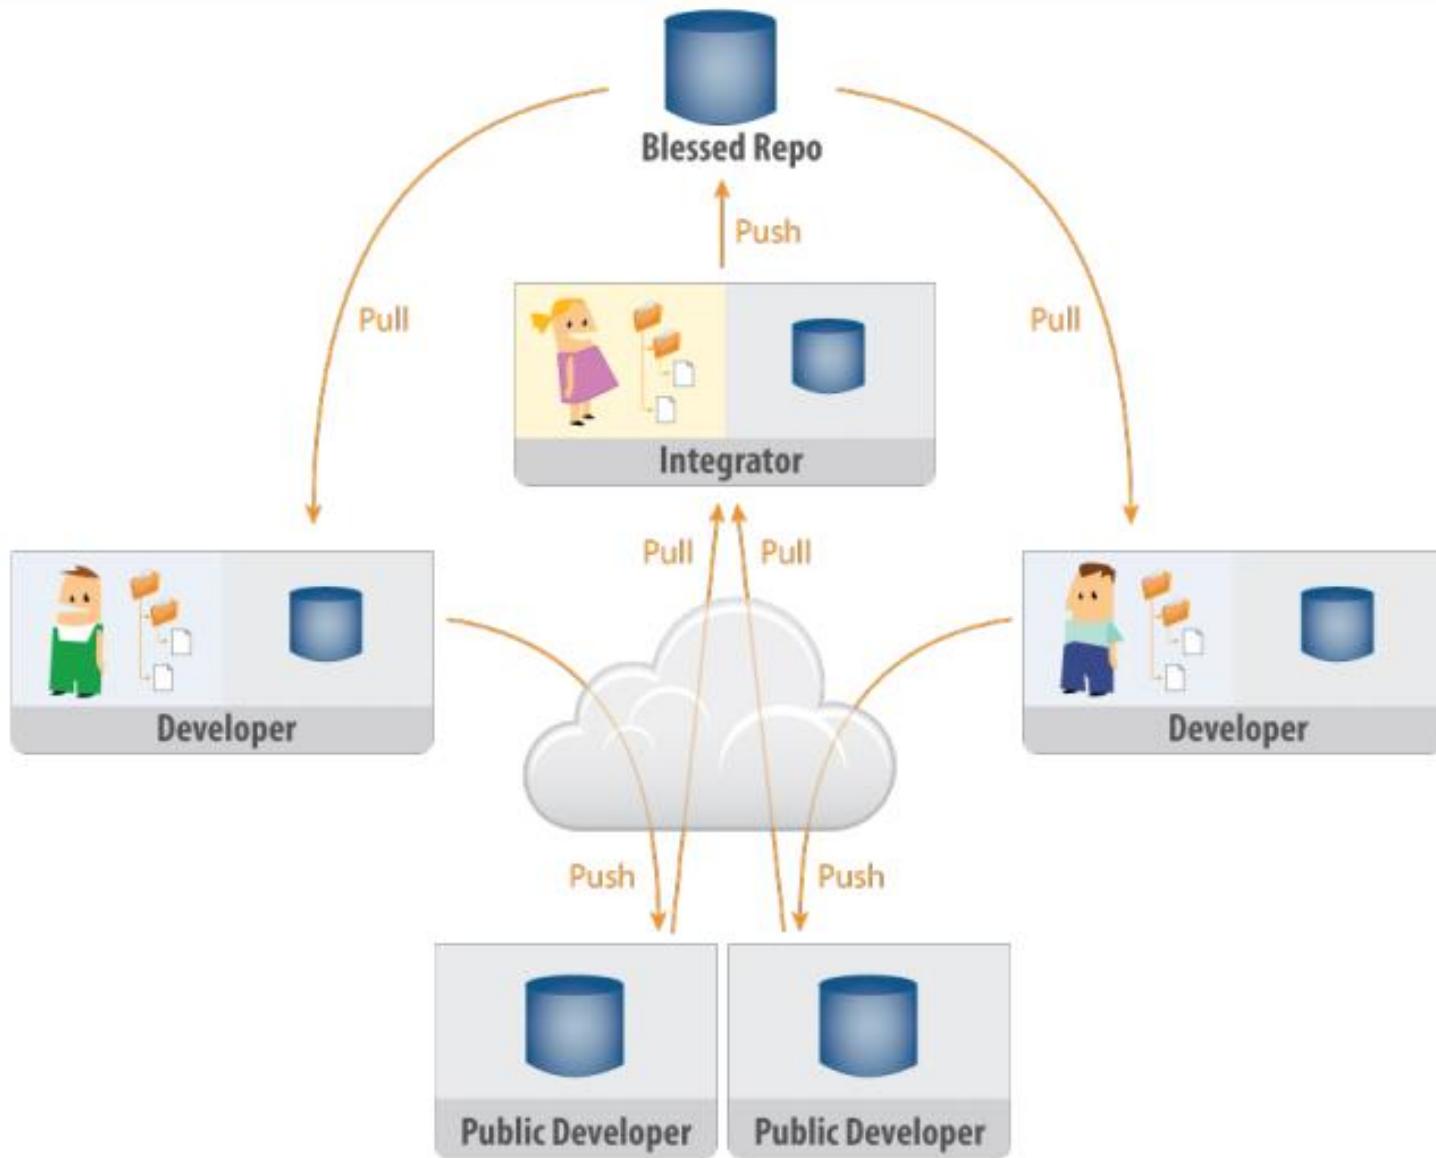

Thanks!

Backup slides

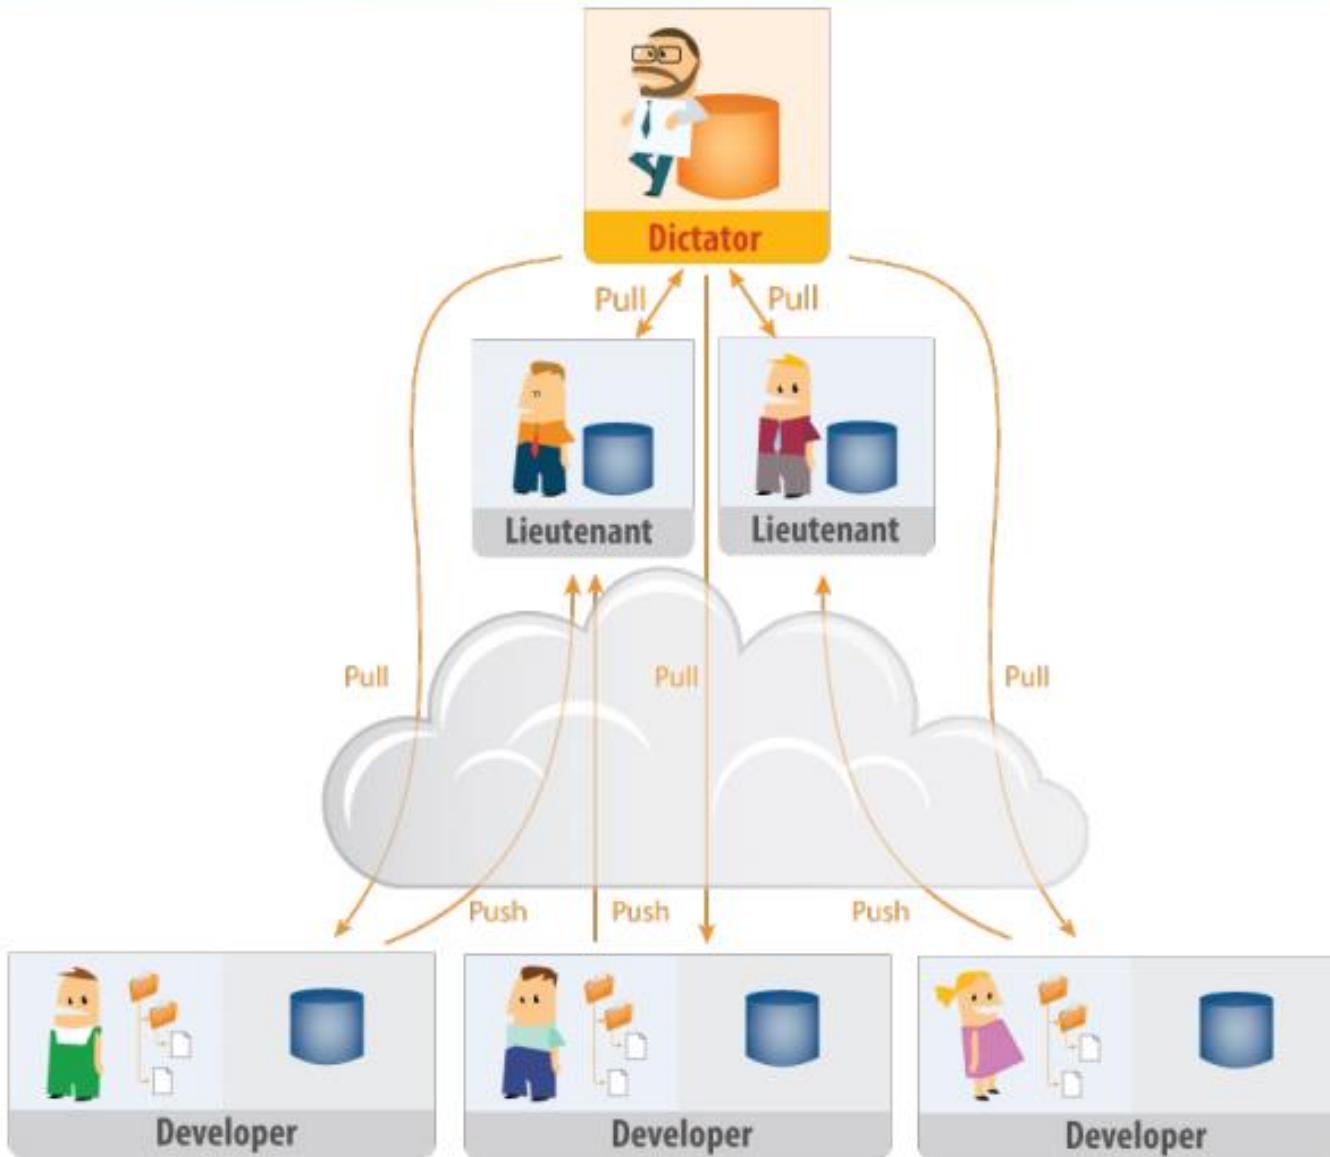

Centralized Workflow

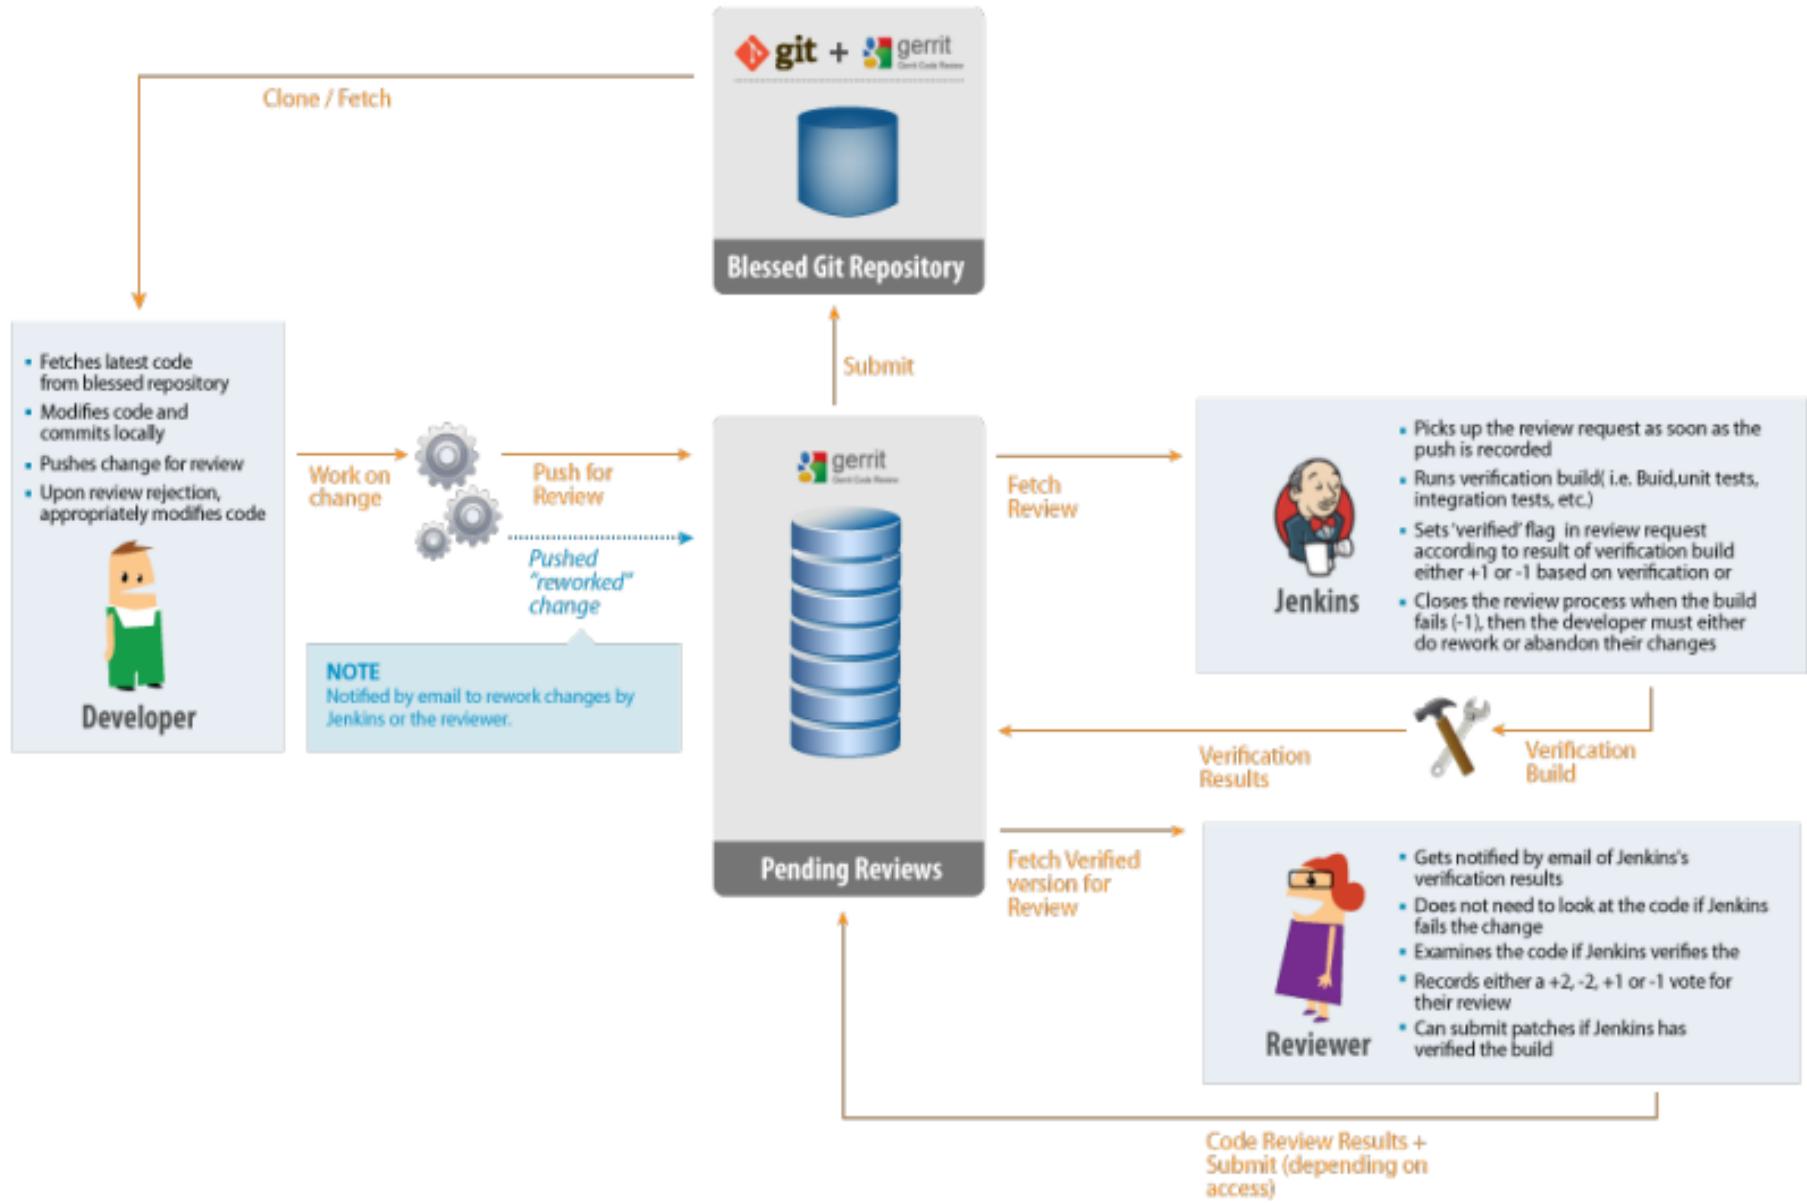

Integrators Workflow

Dictator / Lieutenants Workflow

Gerrit Code Review Workflow

Detached HEAD

If you checkout any commit SHA1, tag, or remote-tracking branch then you will end up having a “detached HEAD”:

```
$ git checkout 494e2cb73ed6424b27f9766bf8a2cb29770ale7e  
Note: checking out '494e2cb73ed6424b27f9766bf8a2cb29770ale7e'.
```

You are in 'detached HEAD' state. You can look around, make experimental changes and commit them, and you can discard any commits you make in this state without impacting any branches by performing another checkout.

If you want to create a new branch to retain commits you create, you may do so (now or later) by using -b with the checkout command again. Example:

```
git checkout -b new_branch_name
```

```
HEAD is now at 494e2cb... Added README file
```

Git stash

You may be in a state where you have some changes that are not ready for committing, but you need to change branches in order to work on something else.

```
sheta@SHETA-THINK ~/my-project (fix-off-by-one)
$ git status
# On branch fix-off-by-one
# Changes to be committed:
#   (use "git reset HEAD <file>..." to unstage)
#
#       modified:   README.txt

$ git checkout master
error: Your local changes to the following files would be overwritten by checkout

      README.txt
Please, commit your changes or stash them before you can switch branches.
Aborting
```

git stash takes current state of your working directory (what is staged, modified, etc.) and saves it as a stack of unfinished changes in **refs/stash**.

```
$ git stash save --all
Saved working directory and index state WIP on fix-off-by-one: ef2f6c3 Release r
e added
HEAD is now at ef2f6c3 Release note added
```

Later you can switch back to the previous branch and apply your saved changes to your working tree to have it exactly the way you had it prior to stashing your changes. You should

Git Master->Slave

Mirroring

Primary

Mirror

What are tracking and remote-tracking branches?

- The combination of these branches defines a relationship between a local branch and one in the remote repository.
- When a repository is cloned, Git automatically creates **remote-tracking branches** (e.g., origin/master) for the remote branches and a **tracking branch** (e.g., master) to allow for local changes in relationship to the remote branch
